The shaft at the Niagara mine, on Deer creek, is now 300 ft. deep. On the 300-ft. level a cross-cut has been started. A blower has been installed. The shaft is being sunk deeper.—An open-cut about 100 ft. long has been made at the Belle Union mine and a cross-cut adit, which is to be driven a distance of 200 ft., has been started. This mine produced considerable gold, when worked years ago, but this work stopped at water-level. As there was good ore in the shaft when work was suspended, the company expects to find ore when they reach the vein.—Robert Johnson has found some good ore in some veins on his ranch, six miles south of Grass Valley. The vein in the shaft, which is 21 ft. deep, is $3\frac{1}{2}$ ft. wide. A pump is to be installed and then the shaft will be sunk deeper.—The first two sets of timbers are now in place at the new two-compartment shaft being sunk at the Midas mine, at Randolph Flat. Two shifts have been put to work, as the shaft-house and blacksmith shop are almost finished. This shaft will cut the vein at a depth of about 70 ft. Some good ore has been found on the Davis property adjoining the Midas and on which the Midas company has a bond.

PLUMAS COUNTY.

Standard and McGill have struck a rich vein of ore in one of the cross-cuts on the Eureka group near Greenville. This ore is said to assay \$30 to \$40 per ton and is all free-milling. This mine is near the Indian Valley property on the same ridge.—During the past month the Indian Valley M. Co. has purchased and taken options on several groups of claims near their original patented locations. It has bought the Treleven homestead, which lies just north of the mine, as they required it for dump ground and as a millsite for the cyanide plant, which the company intends to build.

Three steam scrapers have been ordered by the Newton M. & D. Co. for their placer mine in Long valley, near Quincy. The gold occurs in a dry hillside gravel; one scraper is in operation at present, its capacity being from

500 to 1,500 cu. yd. per day, according to the bedrock and the gravel. The cost of handling the gravel is stated to be from 3 to 5c. per cu. yd. S. T. Norris is superintendent.

SIERRA COUNTY.

The main tunnel at the South Fork property, near Forest, is at present almost 4,900 ft. long and very close to the Maple Grove line; as soon as that point is reached, a raise will be driven to the channel, which, owing to the character of the ground, is thought to be quite near. This company owns a long distance along this channel which, when worked in the Bald Mountain property farther north, yielded several hundred thousand dollars.—The boarding-house at the West Point mine, near Monte Cristo, was burned last week.

YUBA COUNTY.

Arrangements have been made so that the contract for the construction of the north restraining wall on the Yuba river near the Bayard Kupser farm has been given up by Mr. Munson. W. P. Hammon and associates have agreed to do the work provided they are allowed to have the gold, extracted from the gravel dredged to make this wall. This embankment will be made much larger than was originally planned by the Government engineer.—The shaft at the Bessie mine, in Brown's gulch, is 20 ft. deep and at that level drifts are to be started both to the north and south to develop the vein, which is from 18 to 36 in. wide. The mine is equipped with a steam-hoist and good pump, so that no trouble with water is expected. This property is north of the Dannebrog, Jefferson, and Pennsylvania mines. J. C. Campbell of Nevada City owns the Bessie.—Charles D. Lane is sinking a shaft to develop the Dannebrog, Jefferson, and Pennsylvania mines at depth. These mines produced a large amount of ore in the past from workings near the surface.

TRINITY COUNTY.

A body of rich ore has been struck at the Bonanza King mine, near Carrville, in the northern part of this county. A full force of men is working at this gold mine. J. F. Littlefield is superintendent.

TUOLUMNE COUNTY.

The Sheep Ranch mine has been closed at least for the winter. For some time past work has been done at this mine in a desultory manner, but it was hoped that the company would straighten out its affairs.—The Imperial mill is about ready to start.—A steam hoist is being installed at the Joy property near the Imperial. As soon as the hoist is installed a force of miners will be put to work.—Negotiations are being made for the sale of the Republican mine.—The annual assessment work is being done at the Rough and Ready mine on Table Mtn. near Montezuma. There is an adit at this gravel mine over 1,000 ft. long but this as yet has not cut the deep channel. Considerable gold was taken from surface workings on this property in early days.—The cam shaft at the Goss mill at Tutletown broke last week and the mill was shut down several days but it is running again.

COLORADO.

CHAFFEE COUNTY.

(Special Correspondence).—W. H. Jenkins is erecting a 200-ton mill for the Mary Murphy Co., to be used in treating custom ores from the surrounding properties as well as ore from the Mary Murphy mine. The plant will be concentrating and cyaniding. It is estimated that this company has 150,000 tons ore in the Mary Murphy and 70,000 in the Black Hawk, which it has leased. They also estimate they have 50,000 tons on the dump at the Mary Murphy. An effort is being made to get the mill under cover before winter sets in.

St. Elmo, Nov. 16.

CLEAR CREEK COUNTY.

(Special Correspondence).—Last week the East Argentine company shipped 100 tons of ore to the Santiago mill in Georgetown, where a concentration of 11 to 1 was made. The concentrate assayed 250 oz. silver, 0.24 oz. gold, 30.5% lead, and $15\frac{1}{2}$ zinc per ton, while the middling assayed 78.96 oz. silver, 0.22 oz. gold, 7.8% lead, and 25% zinc per ton. This ore comes from the blind lode intersected 2,125

ft. from the entrance of the adit; this orebody is from 2 to 3 ft. wide. Some first-class ore occurs in a streak varying in width from 12 to 18 inches.

The Sidney adit is now 2,800 ft. long. Work at this property will continue throughout the winter and M. Sidney, who is manager, states that regular shipments will be maintained.—Work was resumed last week at the property of the Leavenworth M. & M. Co., situated on Payne's peak. The lower cross-cut, now 100 ft. long, is to be driven to cut the B. B. lode No. 1, which looks well in the upper workings. It is expected that the vein will be reached within 75 ft. R. H. Blackman is superintendent.—Shipments are being made from the Cram vein, which is being worked through the Doric adit; the vein was cut 2,400 ft. from the portal of this adit. Stopping is in progress upon a body of smelting ore; the vein is 3 to 4 ft. wide in this stope, which is 115 ft. long. The ore being shipped assays \$137 per ton in gold, silver, lead, and copper. The ore sent to the mill assays \$19 per ton, and is concentrated 5 into 1.—A strike was made this week in the Centennial mine, situated in Georgetown. In catching up a cave in the main adit, a streak of smelting ore was found which is 4 to 6 in. wide. Some assays gave 2 to 2½ oz. gold and 25 oz. silver per ton. The discovery was made 400 ft. from the entrance of the adit near the orebody which was mined about seven years ago; it is believed that this is a continuation of that ore-shoot. Stopping is to begin in a few days. H. Ratholz & Co. are operating this block of ground under lease.—In the Centennial adit, which is being driven on company account, a body of heavily mineralized quartz has just been cut at a distance of 500 ft. from the portal. Several stringers of high-grade ore occur in this quartz, and David Kennedy, the manager, thinks that a rich body of smelting ore is near by. Considerable work is being prosecuted on the 500-ft. level from the shaft workings, and a body of ore assaying in places two ounces gold is being followed which varies in width from 18 in. to 3 ft. A fair output is being made at the present time.—At the Mineral Chief mine, while driving the Brown or sixth level, an orebody of medium grade, 4 to 6 ft. wide, is being followed. The ore is left standing until the new 50-ton concentrator, being built just below the Georgetown depot of the Colorado & Southern, is finished. No amalgamation is to be used in this mill, as the ore found in the Mineral Chief workings is inclined to be somewhat zincy. F. A. Maxwell is superintendent of the mine, while Frank Graham is in charge of the concentrator.—At the Muscovite property, the old workings have been cleaned out and retimbered, and the adit is being extended so as to gain greater depth. E. E. Grubb of Georgetown is superintendent of the Muscovite.—The Terrible property, situated on Brown Mtn., has been leased to Wm. Wood, who has agreed to keep the compressor plant in steady operation. A number of sub-leases have already been granted and several of these lessees are shipping ore. The concentrating ore is to be treated at the company's mill. The Terrible-Dunderberg property has produced several million dollars of ore, and most of it assayed over \$100 per ton in silver and lead.—The aerial tramway being constructed by the Santiago M. & M. Co. is nearing completion. This tram is to be one mile in length, the terminus of which will be at the Wilcox tunnel on the line of the Argentine Central Ry. Ore-bins have been erected, and by means of chutes the ore can be dumped into cars for shipment to the company mill and sampler in Georgetown. The Santiago is now being operated under the leasing system. Wm. Rogers of Georgetown is general manager for the company. Georgetown, Nov. 18.

MICHIGAN.

ONTONAGON COUNTY.

The Adventure Consolidated Copper Co. has levied an assessment of \$1 per share, payable November 16 to 27; \$20 has already been paid in on this stock. Explorations with the diamond-drill are still being made on the Baltic formation at this property. Mining operations are confined to No. 3 shaft.—The Lake Copper Co. has found some rich copper ground in its shaft on the Baltic formation. One mass of copper weighed half a ton, while a number of

smaller chunks have been taken out.—The old Union shaft is being unwatered by the Calumet & Hecla Co. Thomas Wilcox is superintendent of this work and also the diamond-drill prospecting that this company is doing on other properties in the Porcupine district, which it holds under option.—The 6 by 8 ft. shaft on the property, belonging to R. P. Mulock, which lies just west of the Copper Crown, is 25 ft. deep. This vein known as the Creek vein, to develop which this shaft is being sunk, looks quite promising at the surface.—Development, made by W. H. Garlick on his property near Union bay, has uncovered a good vein of copper ore 8 ft. wide. This vein is in sandstone and is several hundred feet west of the formations formerly prospected in this property.

NEW MEXICO.

GRANT COUNTY.

(Special Correspondence).—The Forrest Queen copper mine, situated eight miles north of Silver City, is being developed under the management of M. D. Gaylord, of El Paso. Within a distance of 700 ft., ten veins were intersected in the cross-cut; samples from these veins averaged 22% zinc, 3% copper, 10 oz. silver, and \$2 gold per ton. A considerable amount of driving has been done on some of the veins, one of which is reported to be 40 ft. wide. A shaft is also being sunk. About 300 tons of ore, coming from near the surface, have been shipped; this ore averaged 11% copper, and 8 oz. silver.

Silver City, Nov. 11.

SOCORRO COUNTY.

M. D. Gaylord, of El Paso, is developing a lead mine in the northern end of the San Andreas Mtn., 28 miles east of Socorro. In the adit a vein carrying 12% lead ore has been cut. There is said to be 5,000 tons of lead ore on the dump; this came from work done by former companies while prospecting this vein.

NEVADA.

CHURCHILL COUNTY.

At present many prospects at Wonder are not working full-handed, and some are closed down owing to the present financial and smelter difficulties, still all the four shipping mines—the Nevada Wonder, Jack Pot, Hidden Treasure, and Vulture—are still working.—The shaft of the Hidden Treasure mine is now 165 ft. deep, and is in good ore.—A rich strike of ore is reported to have been made last week on the 500-ft. level of the Nevada Wonder.—The Quartzite is sinking a new shaft; this will be sunk to a depth of 200 ft. before any driving is done. The area at Wonder, through which ore is scattered, is 4 miles wide by 6 miles long. The camp is at present about 14 months old; it is 61 miles from the railroad.

ESMERALDA COUNTY.

The output of the Goldfield district for the week ending Nov. 15 was 4,939 tons, having an estimated value of \$456,450. When one considers that the Little Florence has stopped shipping and that the Mohawk Jumbo is closed, when one also bears in mind that the smelters are refusing all ore below \$60 per ton and are increasing the smelting rates, this output indeed is remarkable. The output of the Little Florence and the Mohawk Jumbo alone averaged almost 3,000 tons per week at the time that they quit shipping. Many of the mines are making only small shipments and are waiting for a clearing up of the financial troubles. The shipments from the different properties during the week were as follows: Mohawk, 1,350 tons; Mohawk Combination, 2,193; Begole lease, 326; Rogers Goldfield Syndicate, 111; Florence Annex, 62; St. Ives Leasing Co., 68; Diamondfield Black Butte, 41; Red Top mine, 53. The Combination treated 595 tons of ore from the Combination mine, averaging \$50 per ton; the Kinkead mill treated 140 tons of Red Top ore, averaging \$45 per ton.—The output of the Goldfield Consolidated for the last six months was 46,644 tons of shipping ore; for the last three months, 29,491; for October, 13,548 tons.—As the Mohawk Combination and the Begole leases only have two weeks more to run, every effort is being made to hoist to surface as much ore as possible. Whatever ore is at surface by the expira-

tion of the lease is credited to it, whether shipped or placed temporarily on the dump. Some very rich ore has been struck on the 275-ft. level of the Begole lease this last week. Most of the Begole tonnage is hoisted through the incline shaft belonging to the Mohawk Combination.—The Little Florence lease has been connected with the 400-ft. level of the Rogers Syndicate lease and surveys are now being made to determine the boundary between these two leases.—The Little Florence is still piling rich ore on the dump at the rate of 100 tons per day. A cross-cut is being driven on the 500-ft. level. Much of the ore mined comes from the 400-ft. level. The company is trying to make arrangements with the Selby smelter to treat its ore.—The orebody recently struck in the Florence Annex is looking as promising as ever. The orebody where it is being developed on the 300-ft. level is 2 ft. wide and is said to average \$400 per ton. The first two carloads shipped from this lease averaged nearly \$600 per ton. The cross-cut on the 400-ft. level has cut the orebody and it is expected that on the 500-ft. level the vein will be reached sometime this week.

(Special Correspondence).—Owing to the scarcity of money, the Consolidated company and the Mohawk Combination lease, operating on the same property, have posted notices stating that the miners would be paid one-half in cash and the other half in exchange drafts. The miners are not inclined to accept these conditions, but realize that until delayed settlements can be made with the smelters, a shut-down might otherwise result. A special meeting of the Miners' Union was called by Charles McKinnon, the president, and after a lengthy discussion a committee was appointed to confer with the mine operators to devise a remedy for the present money stringency. The miners want the smelters to send all Nevada bullion direct to the mint and to demand coin therefor; that the smelters then pay for ore in cash, and that the mine owners pay their men in cash, as soon as this arrangement can be satisfactorily put into operation.—Several leasing companies have suspended operations, being unable to continue without funds, which are temporarily tied up in the Nye & Ormsby County Bank and the State Bank & Trust Co.—It is of common occurrence in Goldfield at the present time for mining engineers and promoters to shoulder a pick and shovel.—John W. Finch has resigned as manager of the Consolidated, and becomes advisory engineer, while John H. Mackenzie has been appointed general manager. Mr. Mackenzie comes from San Francisco, where he is in partnership with F. W. Bradley. He was formerly superintendent of the Independence at Cripple Creek, and then manager of the Le Roi at Rossland, British Columbia.

Goldfield, Nov. 18.

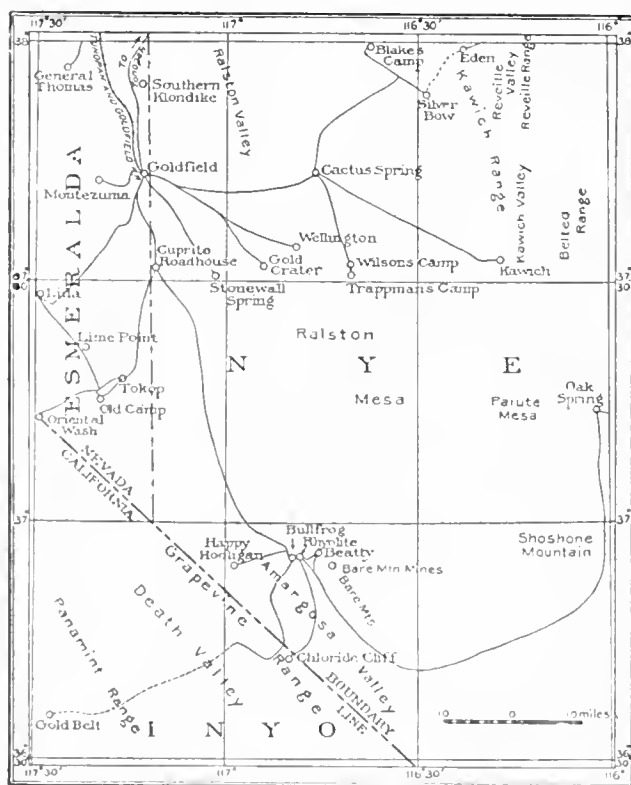

EUREKA COUNTY.

The Osceola mine at Palisade has increased its force to 25 men. A winze is being sunk on the ore-shoot recently found in the cross-cut. This mine ships each month two cars of high-grade silver ore carrying some lead and about 3% copper.—The Palisade-Pittsburg Co. is still driving the cross-cut adit; this will cut the vein at a depth of 300 ft. Twelve men are working at this property. At surface the vein-capping is over 40 ft. wide.—A vein of good copper-silver ore has been cut by the adit on the Hankins group of claims.—Walter Morrissey and partners have discovered an 8-ft. vein of lead-silver ore on their group of claims adjoining the Palisade-Pittsburg property.

NYE COUNTY.

(Special Correspondence).—Affairs are looking rather blue at Rhyolite, for, owing to the tightness of the money market, practically all the prospects in the Bullfrog district have been forced to shut down. At present 100 men are employed in the mine and mill of the Montgomery-Shoshone Co., but there are only 75 to 100 men employed at all the other properties in the district. The Tramps Consolidated, the Montgomery Shoshone, the Bankers National, the Homestake-King, the Amethyst, and the Phillips & Moesser lease on the Gibraltar are working. The Mayflower has shut down, but it still intends to build the mill; underground work has been stopped at the Goldbar until the mill is built.—The Tramps adit is still being driven ahead. The

Denver shaft is now 500 ft. deep and still in ore. The Denver vein has been faulted three times in this distance, but it has been recovered each time after a little prospecting. Some ore is being shipped from this shaft, as much of the ore is high-grade. At the Eclipse adit two good shoots of milling ore have been developed, while in the Hobo there is also some good milling ore. A full force of men is working at the Tramps properties.—At the Montgomery Shoshone work is progressing quite satisfactorily. The mill is doing good work and much ore is being shipped; at present about \$1,000 of amalgam is being cleaned up from the plates each day. It is expected that the company will ship about 4,000 tons of ore to the Salt Lake smelters this month. This tale ore assays about \$100 per ton. The Polar shaft is 300 ft. deep and has been connected at that level with the main Shoshone shaft, through which the hoisting is done. This is a 3-compartment vertical shaft at present 570 ft. deep; sinking is still going on in this shaft. Levels are run at

Part of Nevada.

every 100-ft. mark. Water was first struck 45 ft. below the fifth level; at present 30,000 gal. per day are pumped from this shaft. Over 12,000 ft. of development work has been done on the Montgomery Shoshone property. Much good ore which came from this development work is on the dump. In the Polar shaft there is considerable milling ore and some shipping ore, but most of the shipping ore comes from the taley orebody in the Shoshone. Twelve air-drills are used at this mine. The compressor and the mill are run by electric power from the Nevada-California Co. power-line coming from Bishop, Cal. The Shoshone mill has a capacity of 250 tons; the ore is crushed in Blake crushers, rolls, and Huntington mills; then it is amalgamated and concentrated on Wilfley tables and Frue vanners; the tailings are then cyanided, the sand being treated in agitators, the slimes in Butters filter-tanks.—Work is progressing slowly on the Homestake mill.—The Homestake-King mill will be running soon.—The 10-stamp mill at the Gold Bullfrog, north of Rhyolite and in the vicinity of the Mayflower, is working about half-time owing to scarcity of water.—At the Pioneer, prospecting is still going on in the attempt to find the vein which has been faulted.

Rhyolite, Nov. 16.

BRITISH COLUMBIA.

The shipments from the mining districts of this province last week were as follows: Boundary, 32,233 tons; Rossland, 5,775; East of Columbia, 4,130; total, 42,138 tons.

Special Correspondence.

Toronto.

Late News.—*Serious Condition of Ore Market.*

In view of the uncertainty of the market for silver and the general financial situation the American smelters are refusing to accept shipments of Cobalt ore. All that is now going forward is being sent under old contracts. As a result, many of the mine-owners are adopting a policy of retrenchment and will reduce their working forces. The directors of the Tretheway have decided only to work a day shift, which will leave only 25 or 30 men employed. A. W. Johnson, vice-president of the Canadian Copper Co., was in town this week in conference with leading mine-owners over the situation, which is regarded as serious.

Cripple Creek, Colorado.

Anchoria-Leland and Ethel Louise Leases.—Increase in Output of District.—Effect of Low Treatment Rates.—Strike in the Red Bird.—The Dante.—A Pumping Agreement.

The Anchoria-Leland and Ethel Louise companies have adopted the leasing system under the single management of William I. Howbert. The western portion of the Anchoria-Leland property, with the shaft-house, has been leased to George E. and F. G. Whip and H. D. Benton, for a period of 18 months. The City View claim of the Ethel Louise has also been leased for a period of 18 months, with a flat royalty.—The Eagle Ore Co. has found it necessary to employ a night force at its sampler for the first time in several months, obviously as a result of the recent reduction in treatment charges. About 600 tons per 24 hr. are sampled. It is reported that the allied railroad lines are hauling more ore at the present time than for many months. The Union plant at Florence has resumed operations and this fact renders a large number of narrow-gauge cars available, relieving the car shortage and the congestion in the Standard plant at Colorado City. There is a well authenticated rumor that still another cut in rates will be announced at the close of this month; 50c. on \$8 ore being the rate in contemplation. The output for November is expected to be exceptionally heavy.

The Ophir is installing a boiler at a new shaft being put down from the surface.—The Cresson mine has increased its output by the installation of an electric tram and Crane washer; the production for November is expected to reach 2,500 tons.—A strike is reported on the Red Bird claim of the National on the outskirts of the city, on the west slope of Gold hill.—The El Paso Co. is planning to resume operations on lessee account in December, although no shipments will be permitted to leave the property before January, the inference being that all ore must go to the Golden Cycle mill on the resumption of operations at that time, and with which the El Paso management has a long-time contract. Lessees, however, can commence work on the 10th of next month, when the hoist at the main shaft will be available. Plats of the underground workings have been completed by T. R. Countryman. The management is already besieged with applications for leases, and all available territory is greatly in demand.

The Dante property is coming rapidly to the front as one of the best producers of the district; the British-American Co. on the South Dante has opened a large body of ore, the walls of which have not been determined, although stopes 20 ft. wide are worked, and the output has been better than a car a day for the past two months, with returns of \$25 to \$80 per ton. R. L. Jame-

son & Co., operating on the North Dante, believe they have cut the extension of the shoot opened by the British-American Co. and that another lease of like value on the same property is in their possession.—The Pharmacist Co. has shipped two cars of a high average, 5 oz. per ton being expected.—John Sharpe is reported to have another rich strike near the surface on the west slope of Battle Mtn., a small seam giving assays as high as \$300 per ton.

The Joe Dandy mill, after three months operation, is reported to be operating successfully on \$5 ore, of which there are large quantities in the mine; 75 tons per day have been handled, but the full capacity of 100 tons is expected to be reached within a month.—An addition to the Isabella cyanide mill is contemplated; two vats are to be constructed of a capacity of 125 tons.—The Ironclad mill management consigned a retort valued at \$2,400 to the mint at Denver, representing a 13 days' run on \$2 ore.—An exceptionally high average has been maintained on ore shipped by Humphreys & Thompson from the Little Clara lease; they obtained \$80 per ton on all ore shipped, or a total production for October of slightly over \$42,000.

A. R. McLeod & Co., the first to obtain a concession under the new leasing system on the Midget property, make an initial shipment of 18 tons to the Portland mill.—The Strong and Portland companies are reported to have entered upon a pumping agreement in order to unwater the lower levels of the respective properties; the combined pumping plants can handle 1,600 to 2,000 gal. per minute.

Salt Lake, Utah.

Smelters Cease Operation.—Effect of Judicial Decision.—Prospects of Resumption.—Utah Consolidated.—Shipments from Tintic.—The Daly West Resumes Work.

The announcement of the closing of the lead and copper smelters of the United States Smelting, Refining & Mining Co., at Bingham Junction as a result of the decision of the Court of Appeals in affirming the decree of the Federal Court of the district of Utah, while it will work a temporary hardship on several mining companies, which had contracts with the smelting company, will do no permanent injury. Outside of the smelting company's own mines in Bingham and possibly two or three mines in the Tintic district there will be no curtailment or enforced shut-downs. As far as the Tintic mines are concerned, the situation will soon be relieved through the completion of the new lead smelter of the Tintic Smelting Co. which will be ready about the middle of January, if not before. This plant can easily take care of the output of the Uncle Sam, Colorado, Lower Mammoth, and Grand Central mines, which have been either obliged to curtail on account of a request from the smelting companies or shut down entirely as a consequence of the closing of the Bingham Consolidated and United States smelters. It is believed, however, that at least the lead smelter of the United States company will be allowed to resume operations to a limited degree. The company has gone to great expense within the past year in the erection of a bag-house for the arrest of the deleterious substances contained in the fumes. In view of the fact that the American Smelting & Refining Co. will be permitted to smelt ores as heretofore at its Murray plant by some amicable understanding with the farmers who appeared as plaintiffs in the smoke cases under a stipulation asking the Court for a modified decree, it would seem that it would be unjust to the United States company to force the latter to retire permanently from the Utah field. The American company has done no more

than the United States company toward retaining the flue-dust, which does the damage to vegetation. It has simply been more fortunate in bringing the farmers around to their senses, and it has required a little ready cash to do it.

The Utah Consolidated copper smelter, near Murray, which was also subject to attack, and which has probably done more damage than all the other plants combined, owing to the heavy sulphide character of the ores treated there, is still in operation, and there appears to be no disposition to close shop until the mandate of the Court is actually given. In the meantime the company's attorneys are arranging to perfect an appeal to the United States Supreme Court, provided the lower court does not feel disposed to modify its order of injunction permitting the company to go on with its smelting of ore until such time that its proposed new smelter can be erected in Toole county. It will take at least a year to build this plant, the site has been selected and practically all the preliminaries arranged preparatory to the letting of contracts. The plans were drawn several months ago by engineers employed by the Amalgamated Copper Co., and are said

sumed actual mining. At the Ontario, however, a force is engaged in the work of restoring the drainage adit.

Butte, Montana.

Smelter Smoke Cases.—Effect of Utah Decision.—Local Opinions.—Barnes-King Affair.—Fresh Reports on the Mine.—Conditions at Butte.

The full text of the opinion of the United States Court of Appeals in the Utah smelter case has not been seen in Butte, but the attorneys for the 'smoke farmers' of the Deer Lodge valley claim the decision is binding on the Federal Court in Montana in the injunction suit against the Washoe and Anaconda companies, in which it is sought to close the big Washoe smelter at Anaconda. The Master in Chancery in the Washoe case found that some damage was being done to the farms by the smelter and that the injury was continuous, but he advised against an injunction on the ground that the defendant companies were able to respond in any amount of damages and that the closing of the plant would be an irreparable injury to the State of Montana and disastrous to several communities, especially Butte and Anaconda. The Master also found that the closing of the smelter would be a great injury to the 'smoke farmers' themselves, as it would take from them practically the only market they now have for their produce. When these findings were announced they were generally regarded as favorable to the companies, though they were not entirely satisfactory to either side, and both have made requests for modifications. In view of the decision of the Court of Appeals in the Utah cases, the attorneys for the farmers say the recommendations of the Master in Chancery cannot be considered by the District Court, but that the latter must, as a matter of course, grant the injunction against the Washoe smelter and can not take into consideration the injury that would be done to the communities or even to the State. However, that is only one opinion; whatever the facts of the decision in the Utah case, the Washoe case is in many respects different. The Master has found from the evidence that the land has not been damaged by the sulphur fume emitted by the smelter, and the damage by sulphur has been the great cause of complaint in Utah. The damage done in Montana has been from the arsenic thrown out by the big smelter stack. It is a fact, however, that the damage by the arsenic was done before the tall stack was built and before the Washoe began saving the arsenic, and now very little of that substance escapes. It is possible still further to curtail that cause of damage and practically save all of it. If that is the case the main source of trouble may be removed entirely. At any rate the closing of the Washoe smelter is still a very remote possibility. As found by the Master in Chancery, the present site of the smelter is probably the most available in the entire State and less damage is done by it than would result if placed anywhere else. The Washoe is the largest smelter in the world, and the most economical of operation. It was erected at a cost of about \$10,000,000. An injunction against the smelter would necessarily result in closing the mines of the Anaconda, Butte & Boston, Parrot, Washoe, Trenton, North Butte, and Coalition companies, all of which have their ore treated at the Washoe.

Reno Sales, geologist for the Amalgamated Co., and E. E. Chase, a mining engineer of Denver, have completed their examinations of the Barnes-King mines. Mr. Chase made his examination for Boston stockholders, and it is not known here what his report has been, but it is understood that his findings in effect confirm the reports made by Messrs. John Gillie and Charles

Montana.

now to be in possession of the executive department of the Utah Consolidated at New York.—Because of the inability to finance its metal product the Utah Smelting Co., which has been operating an independent copper smelter near Ogden during the present year, has ordered the fires drawn. The plant has been treating about 250 tons per day.

Ore shipments from the Tintic mining district last week amounted to 101 carloads, the contributing mines and amounts being: Beck Tunnel, 2; Colorado, 5; May Day, 5; Yankee Con., 4; Uncle Sam Con., 3; Eureka Hill, 3; Centennial Eureka, 15; Bullion Beck, 1; Lower Mammoth, 9; Mammoth, 6; Ajax, 2; Carisa, 1; Scranton, 7; Godiva, 1; Tintic Iron, 7 carloads.—The ore and bullion settlements reported last week by Salt Lake banks amounted to \$461,000.—The Daly-West Mining Co. has resumed operations at Park City after a shut-down of about seven weeks, brought on by the strike of miners, who took offense at the management for discharging a union shift-boss, followed by a refusal to reinstate him to his old position. The men have gone back to work under a new schedule of wages agreed to by the operators of the camp and which amounts to a reduction of from 25 to 50 cents per day. The Daly and Ontario companies, under the same management, have not re-

W. Goodale as to the low grade of the ore and the limited quantity of ore available. Mr. Sales made only a geological examination, and that was not encouraging for the stockholders. His observation as to the ore in reserve also confirms the findings of Gillie and Goodale. The present directors of the Barnes-King have declined to bring suit against the former directors and the promoting syndicate to recover some of the money alleged to have been fraudulently obtained and disbursed, and some of the stockholders are now moving to bring such action themselves. The Barnes-King mill had been shut down for some time, owing to the fact that the supply of cyanide ran short, but operations have been resumed. The old shaft on the property is being sunk deeper for the purpose of getting under an orebody recently cut by a diamond-drill. The ore, as disclosed by the drill-cores, is very low-grade, and unless richer deposits are found it will not pay to exploit. The mine at present is not paying expenses and the treasury is gradually being exhausted by the development work.

Stories have been published about alleged business depression and gloom in Butte on account of the curtailment of copper production and the consequent reduction of the number of men employed in the mines. There is anything but gloom apparent in Butte, and no sign of business depression is yet in evidence. Notwithstanding the fact that the Butte mines are at present producing but little more than a fourth of the normal amount of copper, the reduction of the working force has not been in the same proportion and the monthly payroll amounts to more than \$600,000 yet. With the exception of the suspended State Savings Bank all the banks of Butte are paying cash to everybody that calls for it, and they are shipping cash to every one of their country bank correspondents who asks for it, which few other cities of the country have been doing. Local conditions did not cause the suspension of the State Savings Bank. There are no idle men in Butte, for all those that were laid off at the mines have left the district or have found employment on the immense amount of railroad construction work now in progress in Montana, much of it near Butte. Men of families and householders have been retained in employment at the mines and they keep Butte as good as any three or four other cities of its size. To see the great crowds of people on the streets, in the stores and theatres, one would not think that half the working forces at the mines had been laid off.

The Pittsburgh & Montana Copper Co. has resumed operations and is running its smelter to the full furnace capacity, treating its ore by the same process used when the smelter was in operation before. It will be remembered that its plant was closed down during the spring of 1906, because the production of the mine was then only about 100 tons of ore per day. Since then, and up to the present time, the company's ore has been treated by the Washoe Copper Co. at Anaconda. This was a good arrangement for Pittsburgh & Montana as long as its production was small, but when the output reached 350 tons per day and the large body of ore on the west side of the property and the 15 ft. vein on the 800-ft. level were developed, the reason for shipping ore no longer existed. The recent published statements regarding the amount of money spent upon an experimental furnace, and the rebuilding of the plant, are without any foundation. The company's product is being treated by the same process as it was during the operation of the plant in 1905-1906, and it is using now, as it did then, the Bagley process, eliminating entirely water concentration and calcination in roasting furnaces. The report current that the company is rebuilding its smelter is incorrect and is probably due to the fact that it is planning to add

large furnaces, capable of melting 500 tons of ore per day, and another converter in order to provide for present production. The buildings were originally built so that additional furnaces and converters could be installed without disturbing or changing other portions of the plant. The Pittsburgh company has quite an advantage over a great many of the other copper producers, by reason of the fact that its ore carries from four to six ounces of silver per ton and a larger percentage of copper than any other mine in Butte, with one exception.

Wallace, Idaho.

News from Coeur d'Alene.—Effects of Financial Stringency.—Idaho Northern Railroad.—The Surprise and Monitor Mines.—Strike in the Virginia.—Transfer of the Idora.

The Coeur d'Alene district is still affected by the money stringency in the East and the low prices of the metals; both factors are reflected in reduced dividends and working forces in some of the larger mines. The list of closed mines gets longer daily, the last news of this kind being the dismissal of between 40 and 60 miners from the Hecla, a well-known and regular dividend-payer. To add to the general gloom, word has just been received that the directorate of the Idaho Northern railroad and the management of the Federal Mining & Smelting Co. have been unable to reach an agreement with regard to the right-of-way through a parcel of land owned by the latter at Kingston, and in consequence of this, construction work on the road is practically at a standstill and most of the hands have been laid off for the time being. The completion of this railroad will open up the entire north side of the district, where there are many mines with ore ready to ship, but all of these are now practically idle on account of the want of railroad accommodation. The railroad would also give a fresh impetus to the gold mining industry of the Murray district, but now, in addition to the Federal company, it is reported that many of the ranchers through whose ground the railroad passes, as well as the placer miners, will attempt to hold up the promoters of the railroad for as big a cash payment as possible, with the result that litigation is sure to follow and completion of the line is materially delayed. It was hoped that the railroad would be completed next year.

No more ore is to be shipped from the Monitor mine in the Saltese district until better market conditions prevail. This mine has been a steady copper shipper and has already declared one dividend. Supplies for winter have been laid in and the development of the mine will continue with a full force of men as before.—An assessment of 1½ cents per share has been levied on the capital stock of the Surprise mine, which recently closed down its concentrator in the Wardner district. The assessment was levied for the purpose of meeting an indebtedness of \$13,784. Since the beginning of the year the mine has been re-timbered and improved generally, including the erection of the concentrator, new bunk-house, and boarding-house, etc., at a cost of \$41,619, while the receipts from the sale of ore were \$30,835, leaving a deficit of \$13,784 still to be met. In the meantime the mine will be developed with a small force until the metal market improves, when both mine and mill will be worked to full capacity.—A 7-ft. vein of silver-lead ore has been struck in the Virginia mine near Carbon Center. The strike was made at a depth of about 180 ft. and about 300 ft. from the mouth of the adit. There is some good shipping ore on the dumps at present and much of the ore recently cut is of good concentrating quality.—The mill at the Rex mine has been practically completed and will probably be operated

before the end of the month. It is designed to handle about 250 tons daily. The lead will be sold to the American Smelting & Refining Co. and the zinc will be shipped to a smelter in Kansas. The mill will be operated principally by water-power, but two motors and electric connections have been installed in case of any insufficiency of supply or interference by frost. The cost of handling the ore will be \$1 per ton.

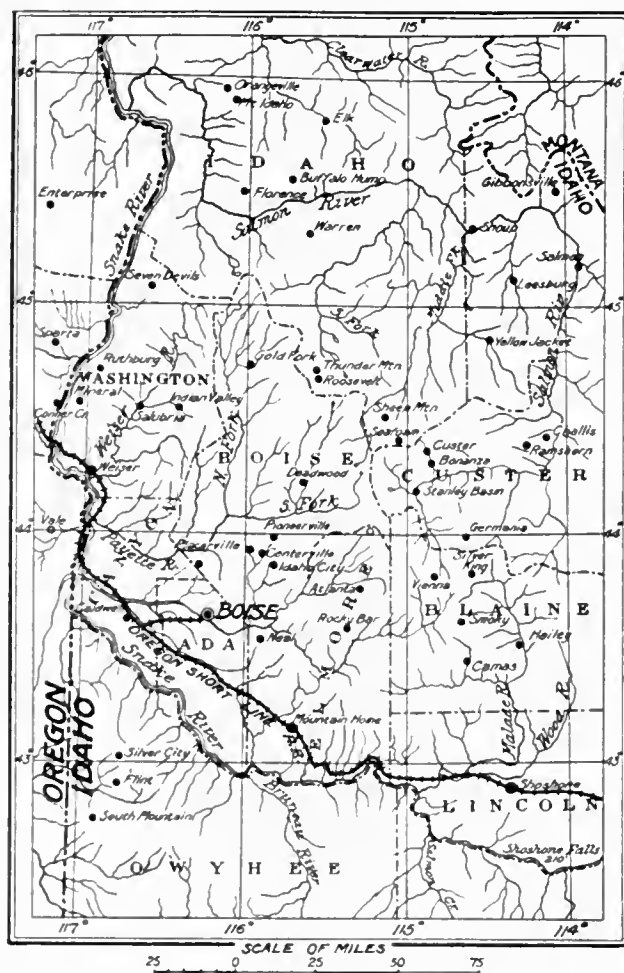

Herman J. Rossi and John H. Nordquist of Wallace have taken over the control of the Idora mine, against which a number of liens were filed by miners and a suit has been commenced for the recovery of the amounts due thereunder. Walter J. Nichols of Spokane has been given a first mortgage on the property and all of the debts have been massed. Notices are about to be circu-

shaft of the mine is full of water, the pumps having been drawn.—A 6-ft. vein carrying six inches of ore has been found in the Trade Dollar mine, at Burke, which is being worked by the Smuggler-Virginia owners under lease. The ore carries zinc and iron sulphides and some galena, and is in a formation similar to that of the Hercules mine.

Chihuahua, Mexico.

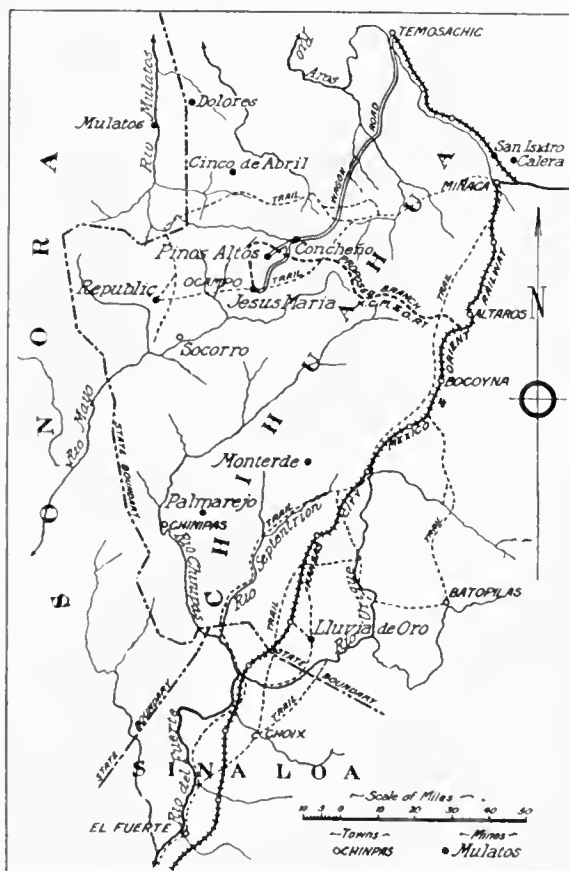

Chihuahua Mining Co.—Successful Work at Santa Eulalia.—A. S. & R. Mines.—A New Tramway.—Santa Eulalia Exploration Co.—San Toy Co.—A Power Station.—Pinos Altos Mine.

The Chihuahua Mining Co., of which Grant B. Schley of New York is president, is operating the Chihuahua and Potosi mines in the Santa Eulalia district. W. J. Quigley of Chihuahua is financial agent, B. L. Farrar being mine superintendent. The two mines are 1,500 ft.

Map of Idaho.

lated among the stockholders giving them an opportunity to take 400,000 shares of treasury stock at 4 cents, and it is calculated that the sale of less than 100,000 shares will cover the indebtedness. An option was given to F. Augustus Heinze on the property in July, but this has not been taken up, and as this stipulated that no treasury stock was to be sold during the time of its existence, the management was of course barred from disposing of any while there was yet a market. After the option had lapsed there was no market for the stock and this accounts for the temporary embarrassment of the company. Development work is to be resumed at once and pushed during the winter under the management of Rossi and Nordquist. The mine has already made several shipments of ore and the erection of a mill is contemplated. —A force of men have been set to work repairing the buildings, etc., at the Vienna International mine on Placer creek, which were recently destroyed by fire. The new buildings will be of corrugated iron, but it is expected that the work will consume at least 60 days. The

Map of Part of Mexico.

apart and their workings are connected. The Chihuahua shaft is 1,900 ft. deep, the several levels that run from the shaft into the orebodies being from the 1,000-ft. station down. At this point is a porphyry overflow, 600 ft. deep, which was passed through before the lime was encountered. The ores, which are a silver-lead carbonate and iron-lead sulphides, occur in shoots within a fissure in the lime. The ore-shoot in the Chihuahua is found to have a maximum width of 300 ft. The carbonate ores are mostly between the 1,000 and 1,500-ft. levels. Below the latter the lead is in the form of galena, accompanied by silver. The sulphide ores are said to be largely of milling grade and therefore a concentrating mill is in contemplation. The Potosi shaft is 1,700 ft. deep, over which is a steel head-frame and a double-cone drum steam-hoist and a Leyner air-compressor. A second shaft on the Potosi has also been sunk to a depth of 1,600 ft. In the Potosi are large bodies of silver-lead carbonates, and richer sulphides than occur in the Chihuahua. In the Potosi are bodies of

zinc carbonates which are distinctly separated from the lead carbonates. The sulphides, at greater depth, are composed of iron, lead, and zinc, accompanied by silver. In the matter of erecting a mill, consideration will be given to the zinc ores and it is possible that magnetic separators will be included in the equipment. The higher-grade zinc ores have been shipped regularly for the past two or three years. This company has its own railroad line, which runs from the Hacienda Robinson, near Chihuahua, to its mines above Santa Eulalia.

The American Smelting & Refining Co.'s operations in the Santa Eulalia district are centred at the Santo Domingo, Velardeña, Mina Vieja, and San Antonio mines, all under the management of W. J. Mitchell. The first three are practically contiguous in the central part of the district, the last named being separated from the others by a short distance. The Mina Vieja is referred to as one of the oldest and one of the richest mines in Mexico. It yields a highly silicious ore, carrying an average of 80 oz. silver per ton. This ore occurs in irregular deposits in the lime, the silver being in the form of a chloride. The Santo Domingo is a heavy producer of ore, carrying 14% lead and 14 oz. silver per ton; the San Antonio ores approximate 18 oz. silver per ton and 24% lead. The Velardeña is not as yet producing, though much has been accomplished in the way of development. The lead ores in these mines are carbonates, associated with iron, carrying from 30 to 40% of the latter. There is some galena, though as yet it is not of great importance. The Mina Vieja and Velardeña are at present being equipped with electric-hoisting machinery, the power for which is generated at the Santo Domingo mine. These mines have been producing from 5,000 to 6,000 tons per month, though temporarily this has been cut down to 4,000 tons. Shipments thus far have been made over the Mineral Railroad to Chihuahua, then transferred to the Mexican Central line, necessitating a change from narrow-gauge to standard-gauge cars; but the plans of the company contemplate the building of an aerial tramway to extend from the Velardeña shaft to the new A. S. & R. Co. smelting plant, situated on the main line of the Mexican Central, eight miles from the mines. It is anticipated that the furnaces of the new smelter will be blown in some time in December. The further plan is to utilize the Velardeña shaft as the main hoisting centre for the Velardeña, Mina Vieja, and Santo Domingo workings. Ore shipments to the new smelter will begin as soon as the plant is ready.

The Santa Eulalia Exploration Co. of California is operating the Buena Tierra mine in Santa Eulalia district. Wm. A. McGee is president of the company; Dr. H. Nelson Jackson is managing director, with Felix Chappellet as assistant manager. The company's holdings embrace 36 pertenencias, part of which were purchased from the Hearst estate. The mine is worked through a 1,460-ft. shaft, which was sunk in the lime, and seven levels from it have been driven into the ore deposit. The first level is 480 ft. below the collar of the shaft. The property is equipped with two Babcock & Wilcox tubular boilers, a 150-hp. hoist, 7-drill compressor, a 75-ft. steel head-frame. The shipping bins are on the railroad of the Chihuahua Mining Co. The ores consist of sand carbonates and galena, carrying about 12 oz. silver per ton, 16% lead, 33% iron, 9% lime, 2% manganese, 13 to 15% silica. Within the last four years shipments of ore have aggregated 125,000 tons. Up to a month ago shipments, which are made to the El Paso smelter, were running 150 tons per day, which now are reduced to half that amount. Like other mines at Santa Eulalia this one is free from water and requires no timbering.

The San Toy Mining Co. owns and operates the Galdeana and the Juarez mines, situated in the Santa Eulalia district. The former is an old property which has been in possession of the San Toy company six or eight years; the latter was purchased last year at a price said to be \$1,500,000 gold, by Chas. M. Schwab and associates, who control the San Toy company. A Trenton Iron Works aerial tramway line, $4\frac{1}{2}$ miles in length, having steel towers, conveys the ore from the Galdeana to the lower part of the foothills, where there are loading bins. From this point the ore is hauled to the Mexican Central railroad over the San Toy Company's standard-gauge railroad, $4\frac{1}{2}$ miles in length. The distance from the Galdeana to the Juarez is $1\frac{1}{4}$ miles, and the two mines are being connected by an aerial tramway of the Leschen type, so that, in a few months, the ore from the Juarez can be delivered to the railroad without the use of pack animals, as is now the case. The main tramway has a capacity of 750 tons per ten hours, while the new line, from Galdeana to the Juarez, will have a capacity of 500 tons. The company is building a central power station at the Galdeana mine, and the intention is to use electric power for the hoist, the compressors, and all other purposes. A steam-plant will be installed to operate steam turbines, by which the generators will be driven.

The Galdeana workings go to a depth of 1,200 ft. and those of the Juarez to 340 ft. While the workings of the two mines are connected, the plan is to operate a central hoisting plant on each group. The two mines are on the San Juan shoot, on which some other properties are located. It takes the direction of a crescent, as to strike, and is a fissure in the lime. The shoot is irregular in width, but it is 200 ft. wide and 100 ft. high in some places. The ores comprise a silver-lead carbonate. Those taken from the Juarez are said to carry 50 to 60 oz. silver and 5 to 15% lead. The ore in the Galdeana is a little lower, but of fair grade. Part of the ore is silicious, part of it high in iron. Shipments now are running at about the rate of 200 tons per day. Much of the mine-work is being directed to developing and blocking out the ore. J. P. Hutchinson, a stockholder in the company, is general manager, with L. A. Dockery, of Chihuahua, superintendent.

The Pinos Altos mine, of which T. N. Barnsdall of Pittsburg, Pa., is principal owner, is situated in the heart of the Sierra Madre mountains, 200 miles west of the city of Chihuahua, being 100 miles by stage from Temosachic, the terminus of the Chihuahua Pacific railroad. The mine is said to have produced ten million pesos in recent years. The holdings comprise a concession of 30,000 acres, with water rights. E. M. Ray, consulting engineer for Mr. Barnsdall, states that there are on the concession many gold-bearing fissures in basalt and porphyry and that there are extensive orebodies exposed ready for milling. The old mill is being rebuilt and modernized, equipment for concentrating and cyaniding having been decided upon. This will include filter-presses. Orders have been placed for water-wheels, electric generator, and motors, the intention being to install a power-plant within the next eight months. The site is on the Mayo river in western Chihuahua, a region that is said to be heavily timbered.

The Calera Mining Co., operating the Calera mine at San Isidro, 15 miles west of Chihuahua, recently completed and placed in operation its new mill, which handles a lead, iron, and zinc sulphide ore, with crushers, rolls, Sutton & Steele dry concentrating tables, and Wetherill magnetic separators. It is claimed the mill is doing satisfactory work. The property belongs to Moore & Schley and associates, Charles Pringle being the local manager.

Toronto, Canada.

Exposure of a Fraud.—Larder Lake District.—New Discoveries at Cobalt.—Ore Shipments.

The revelations made in the course of the trial of the charges brought against Law & Co., mining brokers, by the *Canadian Mining Journal*, will certainly result in the suppression of wild-cat flotations, for a time at least, whatever may be the immediate issue. The hearing was resumed on Nov. 6 and has since been continued, resulting in a thorough exposure of one of the most villainous swindles ever perpetrated under the pretence of mining. Briefly the facts brought out are these: The defendants, Frank Law, Lockhart Russell, and W. A. Abendroth, comparatively recent arrivals of unknown antecedents,

shares. Then Frank Law sold to Law & Co. \$1,000,000 of his shares for \$50,000 in notes; and Law & Co. put these shares on the market at 10c. each. No other stock has been offered, the defence advanced being that the defendants as directors of the Highland Mary, cannot be punished for what they did as members of the firm or Law & Co. Abendroth, who is secretary of both companies, admitted under examination that he knew nothing of the affairs of the Highland Mary, did not know what title, if any, they had to their claims when he was appointed secretary, or what salary he was to get. He was, he said, merely a figure-head, and signed the prospectus without knowing whether the glowing statements it contained were true or not. The prosecution called J. C. Murray, editor of the *Canadian Mining Journal*, to testify as to the condition and value of the 30 claims, but his evidence was ruled out on a technicality, as the charge was not one of fraud. As a matter of fact, on 15 of these claims there is no outcrop, and nothing of value has been found on the others. No development work whatever has been done, which is hardly surprising, as there has been no money to do it with, as all the receipts from the bargain-counter sales have been absorbed by Law & Co. Moreover neither Law & Co. nor the mining company have any title to the property, as patents are not given until 240 days development work has been done on each claim, and the certificate is liable to cancellation in case no valuable mineral is discovered. The effect of the trial will undoubtedly be to cause a prompt inspection of these properties now that the Government has been aroused to take action.

Larder Lake generally is in a bad way. According to the report of a recent visitor all operations on the Blue Bell and Lucky Boys, two of Law & Co.'s flotations, have ceased and the shaft of the Blue Bell at Spoons Bay is full of water. The Larder Lake Proprietary Gold Fields has suspended operations for lack of funds owing the workmen three months pay. A party of them were met returning to civilization destitute even of money to buy meals. At the Harris-Maxwell, one of the more promising mines of the camp, some work is being done. An exploratory adit is being run 120 ft. near the water-level to cross-cut a dike, the company waiting until the snow flies to bring in machinery. The dike material shows a small amount of galena and iron pyrite and occasionally free gold.

A number of new finds have been made at Cobalt recently. At the Silver Leaf a silver calcite vein with a surface width of 2½ in. has been discovered at about 5 ft. from the main vein. The shaft on the latter is down 45 ft. and a carload of ore, one-half of which is high-grade, has been taken out.—A vein of cobalt and smaltite with silver contents has been found at the Bailey Cobalt in No. 1 adit. In the course of driving at the 115-ft. level in the Cobalt Central a cross-vein 6 in. wide carrying niccolite, smaltite, and silver was struck. Ore shipments for the week ending Nov. 2 were 237 tons; Foster 33 tons, La Rose 124 tons, McKinley-Darragh 60 tons.

The British Canadian Smelters Ltd. has begun the treatment of Cobalt ores in Toronto, two carloads having been forwarded from the La Rose mine. They claim to have a new and economical process, but the noxious fume proved an unsatisfactory feature, as the establishment is situated in the business centre. As the result of complaint to the authorities, they were fined \$50 and costs. The company has asked the city for a site in Ashbridge's marsh and in return for a grant of 25 acres it is now stated that they will erect a smelter employing 500 men.

A Part of Ontario, Canada.

constitute the firm of Law & Co., mining brokers, who floated several Larder lake companies, including the Blue Bell, Lucky Boys, and Highland Mary, all with big capitalizations, and shares marked down to bargain-day figures.

The present action relates solely to the Highland Mary, which has recently been extensively advertised, the stock being offered at 10c. per dollar share. The information charges the defendants as directors with issuing prospectuses that failed to contain the particulars required by law as to the price paid for the property, amount of promotion expenses, commissions, etc. The company was capitalized at \$3,000,000 in one dollar shares and purchased from Frank Law, the principal promoter, 30 claims at Larder Lake, giving him \$2,000,000 in

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A MULE LOAD is from 200 to 300 lb.; a burro load, 125 to 200 lb.; a llama load, 50 to 75 lb. Loads are made up in packages of 25 to 50 lb. each.

A NOVELTY in tin-ore dressing in Cornwall is the use of the Ferraris ball-mill for crushing the ore. A single mill crushes 2,240 lb. of ore per hour to pass a 30-mesh screen, requiring seven horsepower.

MANY HOISTING-ROPEs in Western Australia are condemned on account of internal corrosion. The Government Engineer advises the practice of opening the rope to examine it before condemning it. During the year only one rope actually broke.

A GOOD FUSE should burn at the rate of 80 to 100 seconds per yard. One that burns faster or slower than this should be used with caution. A fuse that snaps when burning, should be immediately condemned. A consignment of fuse should always be tested for regularity and speed of burning before it is approved by the mine superintendent.

THE *Lusitania* in her last voyage, ending at New York on November 8, made the Atlantic crossing in 4 days 18 hr. 40 min., which is the record, being 1 hr. 40 min. better than her previous performance. The best day's run was 618 knots. She encountered a severe storm, the waves being estimated at 50 ft. in height. This is tremendous, as experienced travelers know.

ELECTRIC PUMPS are now used at the Lindal Moor iron mines at Lindal-in-Furness, England. A 3,000-volt three-phase current is used. The special feature of this plant is that, although there are several motors underground, each of these is under the control of the powerhouse engineer; the starting and stopping of each and the throwing in and out of the resistance coils are effected by means of the switch-board apparatus. By means of indicators the engineer can judge the state of affairs at each motor.

ORIGINALLY gold mining in Russia was allowed to all persons enjoying legal rights of citizenship, Russian subjects as well as foreigners. But in 1885 this was restricted so that an exception was made of the 'Sea Region' (the shores of Tatarski Strait and the Japanese Sea, as well as the Sakalin), where Russian subjects only were allowed to mine. In 1902 the law was modified so that foreigners are again allowed to mine in this region, except for the strip of land 100 versts wide along the coast in this, the 'Sea Region.' At present there is an agitation in Russia to remove even this restriction.

AN interesting use to which gypsum is put, especially in England, is the 'burtonization' of beer. The reputed excellence of certain British beers, notably those of Burton and Newark, is attributed to the presence of calcium sulphate in the natural water used in their preparation. It has been calculated that 350,000 lb. gypsum are annually imbibed in potations of Burton beer, and since gypsum is soluble to a certain extent, attempts have been made with varied success to add similar artificial salts to water not derived from gypsum-bearing beds, and large quantities of gypsum are purchased by brewers in England for this purpose. This addition, although advantageous, does not produce so perfect a combination of

salts as that existing in the natural waters of Burton-upon-Trent.

THE Kolar district in Mysore, India, is characterized by narrow rich veins of gold ore. The ore occurs in a band of schist in a granite country. There are two principal lodes, the Champion and the Oriental. Mining on the Champion lode has been successful, that on the Oriental not. One of the mines has been opened to a depth of 3,000 ft. on the incline, others to a depth of 2,000 ft. The veins vary from 1 to 5 ft. in width; the ore mined averages a little less than an ounce gold per ton. The Champion lode is characterized by the great continuity of its ore-shoots in depth. Apparently the veins in this district increase somewhat in width with depth.

IN prospecting an orebody it is well to follow the vein until the amount of ore developed warrants the expense of more direct means of access to it, such as a vertical shaft or an adit. On the other hand, staying with the ore can be carried to an extreme in the case of a developed and paying mine. It is always good policy to drive occasional cross-cuts into the foot-wall and the hanging wall in order to prospect them. If these cross-cuts are judiciously placed, the waste rock coming from these can be used to good advantage as filling and the real cost of this prospecting, owing to the saving in the cost of filling due to this handiness, will be somewhat diminished. Butte owes as much of its development to cross-cutting as it does to sinking and driving. Tons of ore in unsuspected places were found in the 'legal' cross-cuts—those forced upon the participants in the Heinze-Amalgamated litigation. The *Coeur d'Alene* owes much of its greatness to 'blind' lodes which have been developed by cross-cutting. Once there was only one vein at the Waihi mine in New Zealand, now they are prospecting 20 veins in that property, most of which have been found by cross-cutting. Similar cases are to be mentioned in all parts of the world. Wild 'tunnel' schemes, so loved by promoters, of course are to be condemned. Leaving the ore to hunt for your mine does not pay, but it does pay after you have developed your mine, to cross-cut in order to see whether or not another mine is at your very door.

IN coal mining the relative merit of exhaust fans and blowers is still a debated question but in metal mining, where their use is confined at present to ventilating hot stopes or long drifts, there is not much question which is the better in each case. The blowing fan sends a quantity of fresh air into the stope or working; this mingles with the foul air and slowly passes out of the working. The suction fan draws the foul air out, picking it up close to the face where it is most injurious to the miners; fresh air comes in to fill the partial vacuum and takes the place of the foul air. In driving a long drift the chief source of pollution to the air is at the face where the smoke and gas, at the time of blasting, and the gas, occluded in the pile of broken rock and given forth later when mucking begins, are the chief causes of vitiation. Consequently for such work it is best to use a suction fan, as it takes away the polluted air as fast as it is formed. A blower simply blows the gas and smoke away from the face where it hangs and bothers the trammers and others. In the case of a hot stope the object is to get fresh cool air to the men at the faces. In such a case a blower is the best, for it sends the air rapidly through the pipe leading to the face, so that it has little time to become heated, and delivers it where it is desired. In the case of a suction fan the velocity of the in-coming current is so slow that it is as hot as the air going out, and the stope is as unpleasant as if no fan were running.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Green Gold.

The Editor:

Sir—I read Mr. Leach's letter and your remarks in the issue of September 21 with interest because, although I have often heard of green gold, I have never seen it except in the form of thin leaves and had begun to doubt its existence. My own observations on the silver-gold alloys (*Proc. Roy. Soc.*, Vol. 71, 1903, p. 161) satisfied me (1) that silver and gold form perfect mixtures in all proportions and do not form any compound; (2) that there is a perfect gradation of color from yellow to pure white as the proportion of silver increases from 0 to 60%, and that the color does not, according to my eyes, pass through green. Nevertheless, my faith in the observations of others has been strong enough to make me invariably describe alloys of gold and silver as of a "greenish-yellow" color. I write now to ask Mr. Leach if it is possible that a cast and rolled alloy never shows a green color unless it is subjected to some pickling process, which somehow converts part of the gold near the surface into the well-known violet or purple condition? A little violet would, of course, turn yellow into green. The part played by the silver would then be indirect.

T. K. ROSE.

Royal Mint, London, October 15.

Cost of Filtering.

The Editor:

Sir—In your issue of October 26, 1907, under the head of 'Concentrates,' a description of the installation and operation of Moore's filter-press at the Waihi mine, in New Zealand, is given, and the statement is made that the running costs of the filter are less than 2 cents per ton of ore treated. According to the figures given, \$18.28, the total cost of treating 220 tons per 24 hours figures out at the rate of 8.3 cents per ton treated. I think if this 2 cents per ton referred to other than the tonnage of slime treated, as the cost of filter-pressing against the total tonnage of ore, reference would have been made to the ore tonnage before giving the costs.

Cyanide Practice at Copala.

The Editor:

Sir—In the issue of the MINING AND SCIENTIFIC PRESS of June 8, under 'Cyanide Practice at Copala' occurs the following: "In regard to the testing for alkali, we first determine the free cyanide by titrating with standard silver nitrate solution to the first faint opalescence without the use of potassium iodide indicator; we then add a few drops more of the silver nitrate to make the opalescence well defined and titrate with N/5 oxalic acid solution using phenolphthalein as indicator * * * It has been found to check closely with L. M. Green's ferrocyanide method * * * it has been adopted on account of its simplicity."

L. M. Green's ferrocyanide method has been in use here for determining 'protective alkali.' The oxalic acid method, given above, fails completely on our mill solutions. Addition of phenolphthalein, after titrating cyanide solution, to faint opalescence, with normal silver nitrate, leaves the solution white and opalescent. L. M.

Green's ferrocyanide methods gives 0.14% protective alkali on this same solution.

The oxalic acid method fails upon solutions which contain much K_2ZnCy_4 as zinc nitrate is formed. According to equation:

This can be presented by adding an excess of potassium ferrocyanide; but what then becomes of the boasted simplicity of the method? Another objection is the fact that dilute solutions of oxalic acid are unstable. When a method for analytical tests is given, it should be complete. It is not complete, unless its limitations are given.

DANA G. PUTNAM.

Tube-Mill Lining.

The Editor:

Sir—Referring to your issue of October 12, page 466; an article on 'Lining for Tube-Mill.' Had not a rather lengthy article been brought to my notice in the issue of another technical journal just received, I would not have felt justified in commenting at present upon the device mentioned in that article, in which is given results of the excellent work done through the use of the lining. Inasmuch as I have known the fairness with which you have always handled such matters, I beg to suggest that you will again give credit to him to whom credit is due.

While I may be wrong in my supposition, still I have seen fit to enter my protest against the use of this device, or at least the assumption of the credit which might possibly be due to others. That I am justified in claiming this device to be my own, I beg to refer you to Mexican patent No. 6,354, issued to me under date of February 22, 1907, which patent recites my claim to what I designate as the Hardinge conical pebble mill now undergoing practical experiments for definite and positive efficiency.

One of the claims of this patent covering the device for a self-forming tube-mill lining reads as follows:

"Un aparato para triturar materiales frágiles que comprende un barril ó tambor, uno ó ambos de cuyos extremos son cónicos, estando un extremo provisto de una entrada y el otro de una salida, y estando la superficie interior del barril provista de proyecciones longitudinales entre las cuales se alojan los trozos ó piezas del material que se está triturando ó los cuerpos trituradores que se emplean para ayudar á afectar la trituración, ó ambos, los cuales constituyen un forro que proteje el interior del tambor ó barril y que se renueva constantemente por sí sólo tal como en substancia se ha expuesto."

Which being interpreted reads:

An apparatus for disintegrating friable material, comprising a tumbling barrel or drum having one or both ends conical, one end having an outlet, and the other end an inlet, the inner surface of the barrel being provided with longitudinal ribs or flanges between which lumps or the pieces of material undergoing disintegration become lodged, or crushing bodies employed to assist in the disintegration, or both, forming a lining which protects the interior of the barrel or drum, and constantly renews itself as set forth.

If I am claiming more than is my due, our El Oro friends must show that this device was in use previous to my original application for the patent on the same, made about a year since.

The original idea of this device occurred to me through the finding of pebbles of all sizes lodged firmly within any open recess of the tube-mill; more particularly, I found pebbles so firmly imbedded within the splayed edges of the siliceous bricks, that it was impossible to remove them without considerable force being applied, which observation I utilized as above stated.

Mexico is the first to publish my patent; I have pur-

posely withheld publicity as much as possible until I was ready to make a positive statement; for, as you are aware, the mining or metallurgical engineer must deal with facts as he knows them, and not state suppositions as facts, when based on laboratory experiments alone.

H. W. HARDINGE.

New York, November 1.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 12.—Editor.]

The Editor:

Sir—In offering the following replies to the questions of T. S., I am giving an opinion formed from a practice which has been largely for investors living in the north-eastern part of the country. Customs doubtless differ in different parts, and consciences also, I suspect.

1. A fee is preferable whenever possible. Both client and engineer have the satisfaction of knowing what the work is to cost at the outset, and the engineer has no fear that he may be suspected of 'putting in time' to increase his stipend if he stays over an extra day to study those minor details which so often seem inconsequent, but may finally be the deciding factor. On certain lines of work, as a small isolated property to be pumped out in the presence of the engineer, with the possibility of caved ground to be opened, when it is impossible to see whether the work will take four days or forty, and the value of the property is too small to justify a fee to cover the latter condition, a *per diem* rate is more satisfactory.

2. Certainly, it seems more businesslike to have a contract, but it is rarely done here, when the engineer engages for a single examination. If he is to act for a considerable period, or is to have an interest in properties purchased, a contract is signed.

3. It is customary in this part of the country to have expenses advanced. Many examinations are made for people of no financial standing, and the fee is also deposited in bank before the work is begun. A man living in Boston may leave for the West and Alaska for a series of examinations, the aggregate expense of which will be several thousand dollars. It would, to say the least, seriously inconvenience most of us to advance this out of our own pocket, while the refund, even if promptly made as soon as the statement for the first examination was submitted, might not become available for the engineer in Alaska until the season was nearly over.

4. An engineer should certainly own those tools and instruments such as are necessary for the proper accomplishment of his work, as the aneroid, compass, camera, etc. Surveying instruments may or may not be included in this, depending on the class of work a man is doing. A good surveyor can be had for \$10 per day and it usually is more satisfactory to engage one near the property, if necessary to do work of this kind. Maps of the property are frequently furnished and may generally be accepted as correct after going through the workings and making a few measurements to check them. Some of the older engineers occasionally make their own assays, as do also some of the younger, but we are no longer expected to have our own assay-offices. Other equipment is charged to the company. If sold at the end of the trip, as in the case of horses, the company is credited. I question whether a man could charge up a fur coat, but I have charged for hip rubber boots when I had to wade daily through a tunnel carrying two feet of ice-cold water, turning them over to the company afterward.

5. With regard to the expenses mentioned under (a), I believe army officers are allowed about 65 cents per day

for tips. In certain Government departments ammunition is not allowed, *per se*, but goes through all right when charged under the head of 'fresh meat.' It would seem that there should be a distinction made in the case of ammunition, entertaining, etc., between expense incurred for the pleasure of the engineer and that for the benefit of the company.

(b and c) A man cannot do good work if he is not in good condition, and this is especially so in the case mentioned where work is to be in the tropics. An engineer who does not give his company the best there is in him is not worthy of the name. Any man who charges for expenses not incurred is a thief, be it traveling accommodations, or for labor, in the shape of padded payrolls.

Other questions under No. 5 must be largely answered by specific agreement in each case. Young commercial travelers are not ordinarily allowed to charge up shaves, shaves, hair-cuts, and baths, while older men who have demonstrated their worth may entertain in private dining rooms at company expense. There is a similar variation in the case of engineers. It is well in these days of investigations to do nothing which cannot be told on a witness stand without detracting from one's reputation. Of course it is business-like to take vouchers, whether demanded by employers or not, from laborers, assistants, and merchants.

6. Periodical reports to employers who are not familiar with mining are often a source of trouble. First impressions are not easily overcome and a few poor assays, received at the start, may result in the turning down of the property by a company even though the engineer may strongly recommend it in the light of complete results. Of course a company may demand anything; and the engineer has an equal right to decline to make the examination.

In answer to 7, 8, and 9, it may be said that there are many things which may be legitimately done under a specific agreement. I may, with my neighbor's permission, enter his orchard and help myself to his apples. If he is willing, I may go before he has a chance, himself, and take the biggest, rosier ones. If his trees hang over the wall toward the road I may gather apples that have fallen there, and then go and tell all the world what glorious fruit may be found in this place. All this would be legal, with the owner's permission, some of it without. But we cannot imagine those men whom we delight to honor as leaders, and as exponents of what life should be, taking the best apples before the owner had a chance, even *with* his permission. Now if a carpenter was employed to make a ladder so that the owner might pick his apples, and was paid in advance for it, and then the carpenter used that ladder, without permission, to mulch the orchard, and owner, of the juiciest fruit, there would certainly be trouble. Verily, what a farce this is when brought down to everyday affairs; to apples in place of stocks! May T. S. never tell what school he comes from lest his questions reflect on its lack of moral tone! And yet, how may one mingle with the commercial world and not have such questions arise?

As T. S. says: "Each individual case introduces diversified conditions." An engineer, returning from an examination in Sinaloa, finds himself at Altata and no boat due for a week. He takes a trip to a near-by district, examines and options a prospect, paying all expenses himself, and returns in time for the boat. His clients have lost nothing, but as they paid the expense of his trip to Sinaloa they should have the opportunity to take the prospect? If they are not looking for additional property I should say the engineer might then take the property to others.

Similarly of No. 9 it must be said that conditions gov-

ern what may be done. Many a small company, operating in a new district, is glad to have information published because it leads others to investigate, resulting in the operation of neighboring properties, more business in the district, and better labor, freighting, and mail conditions. On the other hand, if a company wishes to acquire as much ground as possible for itself, the less said about the district the better. Whatever is written should be submitted to clients before publication.

10. Many demands for an examination are not in a form to be answered by 'Yes' or 'No.' An engineer on the road often receives a telegram like this: "Proceed to Pioche at once and examine Daylight mine. Wire summary of report as soon as possible." Such a message requires a statement of facts concerning development, values, equipment, and general mining conditions. Reports of this type are common for clients experienced in mining who are competent to reach their own conclusions. Other examinations are made because the owner wishes advice as to development and equipment. Often these are for small companies that have been led into some scheme by an optimistic promoter or prospector who has been put in charge of the work and failed to produce dividends as promised. Frequently an engineer has to report to an investor that a property does not justify the price asked but would be worthy of purchase at a smaller figure. Or he may report that a prospect does not justify purchase at all, but does show values and geological conditions justifying development if a bond can be had. In this case the development to be done should be specified.

Unwatering, or opening caved ground, is ordinarily done by the vendor, or by agreement beforehand. An engineer is not expected to wait until a mine is made. I should say he would be justified in expending but little for the purposes mentioned, without definite authority.

GEO. A. PACKARD.

Boston, October 24.

The Editor:

Sir—In your issue of the 5th ult. there appears a communication entitled 'Searching Questions.' In it occurs a paragraph "If we could get answers to some of the questions from several men, we might deduce a series of useful rules." I take pleasure in contributing my answer for such percentage of service as it may afford toward the deduction of this series.

The ten questions all seem to be predicated on the assumption that the examination is to be made by a comparative novice, and my answers will be made on that theory.

Whether a straight fee, or a *per diem* charge shall be the basis of the remuneration must depend upon the nature of the case. If the young engineer feels that the benefit to himself in experience and information gained will be of more importance than the money consideration, he would be justified in accepting what the contracting party is willing to pay, which would generally be a predetermined fee. The size of it will depend upon how good a trader he is. If the transaction is on a purely business basis a *per diem* should be charged. That leaves the extent of time devoted to the work to be settled after the engineer finds on the ground what the actual conditions are.

All business agreements not closed when made by cash, note, or acceptance (or its equivalent) are based upon contract, expressed or implied. The prudent business man always reduces these contracts to writing. Then each side understands the terms and can always refresh the memory, which is proverbially treacherous. A

young engineer who attempts to do important work without such written contract is inviting trouble.

All the probable expenses of the trip should be in bank to the irrevocable credit of the young engineer before he starts on his trip. The engineer "starting from Colorado bound for the tropics" who adopts any other course is courting an opportunity to become acquainted with some Spanish American jail.

"All the equipment necessary for the work, outside the personal expenses of the engineer," excepting the technical literature and apparatus, which every mining engineer should own, should be paid for by the party hiring him and should be the exclusive property of such party. If sold when no longer needed the amount realized should be credited. Every engineer ought to own a barometer, transit, tapes, and a camera, but it sometimes happens that it is better to hire for the purposes of the examination. In that case the rent is properly chargeable, as a rule, to the party for whom the examination is made. The reason for this charge, however, should be explained.

Tips, laundry, tobacco, ammunition, whiskey (in moderate quantity) are proper items of expense.

If the engineer regards himself as a first-class man he is entitled to associate with men in his class on the trip. Such men always travel first-class. His time on the trip belongs to his employer. It is his duty to travel in such way as to make that time tell to most advantage. He is entitled to allowance for first-class accommodations. If without detriment to his efficiency he can travel for less than first-class cost, the engineer would probably be within his rights if he pocketed the difference, but he would be violating good ethics, and if the practice became known it would be decidedly to his discredit. This is a question upon which engineers differ, but all reputable ones seem agreed that the proper way is to charge for just what is paid out.

No positive rule can be laid down for the particularity with which accounts should be kept. Such items as meals, street-car fares, porters, shoes shined, shave, hair cut, and tips to waiters could be lumped by the day. Telegrams should be kept separate. Vouchers should be taken for such expenditures as vouchers are ordinarily given for, as hotel bills, supplies, and wages. It is not customary to take vouchers for railroad tickets, meals at restaurants, or porters. The more businesslike the expense account, the more satisfactory will it be to the employer, as a rule, and the careful engineer will try to establish a reputation for doing everything carefully and thoroughly. The engineer is sent after information. If he has to pay to secure it the expenditure should be entered on his cash account, whether it be for wages, official fees, money paid out for meals, drinks, cigars, livery teams, fandangoes, or what not. He is sent to secure information and trusted to use his discretion; and his employer agrees to pay the bills.

If the expedition is to last three months the question of when accounts should be rendered should be settled in the contract. In the absence of special provision for periodical expense accounts, they should be rendered with the report and final bill. It is best to keep closely in touch with the employer and to furnish him with such information as he desires as often as he desires, in reason.

The question of what an engineer may do to advance his own interests, whether in buying shares, mining ground, or anything else of value, of publishing information, etc., depends upon what effect any such conduct might have on the employer's interests. These interests it is the duty of the engineer to protect. If, doing that to the fullest extent, he can serve his own as well, it is his privilege.

To the broad question, "Is it permissible to use information gained at company expense for private gain, during or subsequent to the term of employment?" the answer must be: "Yes, decidedly." It may have been for that very purpose that the engineer has accepted the commission.

Question 10 is too indefinitely stated to justify an answer. If the employer's question is: "Shall I take hold of this property?" The engineer must give positive advice. If the question is: "Is this property worth \$100,000?" the engineer must answer: "Yes," or "No; not so far as has been disclosed to date."

"What the engineer should do when the mine is old, caved, and full of water must be determined by his contract and instructions and not by any series of useful rules.

JAMES W. ABBOTT.

Pioche, October 17.

The Mine-Foreman.

The Editor:

Sir—In the matter of 'Deep Thinking and Fast Sinking,' I would like to put in a plea for that class of men who rarely, if ever, get a word of praise or recognition in the scientific papers when anything in the shape of a 'record' is being mentioned in connection with mining. I refer to the mine-foreman. I venture to say that the gentlemen singled out as deserving special mention (Messrs. Brodigan and Simpson), would themselves acknowledge the brunt of the work in creating the 'record' was borne by the foremen, then in all fairness I ask why should he not have the credit? It was he who had to supervise and personally direct the working of everything from the time the holes in the shaft were started until they were blasted and mucked out. Speaking from ten years' experience, there are very few general managers who would be worth their room in the bottom of a shaft planning holes and handling men, yet when a good showing is made the G. M. gets the 'write-up,' and the foreman is not even mentioned. I would also heartily endorse what Mr. P. S. Williams says, namely, that one has to take the conditions into account to judge whether or no the record is an exceptional piece of work. As an example I would state that during my career I have had charge of operations where we sunk 110 metres in less than three months, but I do not consider it such an accomplishment as that of another instance where we were 10 months sinking a bare 25 metres. This shows that good measurement is not much of a criterion unless the conditions are considered along with it. Under the plea then of rendering unto Caesar the things which are Caesar's, I would ask that a fair share of the credit for rapid shaft-sinking be given to whom it is due—the mine-foreman in charge of the work.

T. SKEWES-SAUNDERS.

Ejutla, Oaxaca, Mexico, November 4.

[We take particular pleasure in publishing the foregoing letter. As good managers, none will be more apt to recognize the economic value of an efficient and loyal foreman, than the two engineers that made a record in shaft-sinking. It is an important function of a good manager to know how to select efficient foremen and shaft-bosses, just as a successful general knows whom to put in command of his brigades.—Editor.]

THE Government of Western Australia has set aside six special detectives to watch the illicit traffic in stolen ore and gold at Kalgoorlie. These men are paid by the Chamber of Mines. It is hoped thus to check 'high-grading.'

Diente, Mexico.

Written for the MINING AND SCIENTIFIC PRESS
By E. McCORMICK.

This camp is situated on the northeast frontal scarp of the Sierra Madre, about 12 miles southwest of Monterrey; here are situated the San Pablo, San Pedro, Zaragoza, and a few other mines of lesser note, the district being reached by a narrow-gauge railroad known as the Mineral Belt.

The mountain is made up of massive limestone, the front being a straight scarp overlooking the valley. The rocks of the region are entirely sedimentary, consisting of shale and limestone, the latter generally gray and made up largely of fossil mollusks. The stratification dips southwest at about 78°, but toward the southeast it flattens to a more nearly horizontal position. The rainfall is large, hence the mountains are riddled by water-courses, but, as there is no material to impede a downward passage, the water-level is low. The ore-shoots are parallel to the mountain slope, hence the tendency is to keep the ore above ground-water, removing thereby the zinc and most of the iron and bringing about a marked diminution in the bulk of original ore, which is soft, porous, and light, causing it to sink and contract, so as to leave vacant spaces above. These water channels depend on the fractures in the rock, the zone of fracturing being as a rule only a few feet wide, weak, and in different directions. The ore is very irregular in shape, so that the only advisable method of development is either to follow the fractures of the ore-zone underground or to prospect at the surface. This zone has three lines of fracture, namely, those parallel to the stratification, transverse to it, and horizontal. The intersection of two of these produces a chimney-like shoot, such chimneys being the watercourses where the circulating waters have deposited ore at the intersections.

All the profitable ore of the camp is above the ground-water, the unaltered ore found below being pyrite, blende, and galena, usually badly mixed, hence unfit for smelting; eventually they will, no doubt, be concentrated. The primary ores have been dissolved and re-deposited as carbonates and oxides, chiefly of lead and zinc, the iron being as oxide. Such lead ore as is at present mined contains about 100 grams of silver and from 12 to 20% lead; when wet, it is a clayey mud, but on drying it forms a soft sand. All gangue material foreign to the rock is lacking, only calcite being found.

The limestone southwest of the ore-bearing stratum is dense, fine-grained, impure, and contains nodules of pyrite; the outcrop, although heavily iron-stained, gives no trace of lead or zinc. Under conditions of alteration, zinc, being more soluble than lead, would naturally be carried farther downward in the zone of oxidation and such a mineral has been found in the lowest part of the workings lying parallel to the walls of the orebody, sometimes distinct from the lead and again in the same stope, as a coating intervening between the lead and limestone. This zinc carbonate runs all the way from 3 to 35%, the higher grade being shipped direct to the United States, while the lead ores are smelted at Monterrey. The camp is a prosperous one, but for the past year labor has been scarce, hence wages have increased from 20 to 25%, the present rate for miners being P1.25 per day.

GAS-ENGINES AND GAS-PRODUCERS are used to furnish power to the Waikino mill being built at Waihi, New Zealand. Coal is burned in gas-producers and the producer-gas is piped to the gas engines, which are placed wherever desired. The coal-tar by-product is saved and will help considerably in decreasing the cost of power.

Smelter Smoke, With a Discussion of Methods for Lessening Its Injurious Effects.

Written for the MINING AND SCIENTIFIC PRESS
By L. S. AUSTIN.

Anyone accustomed to smelting conditions as they formerly existed in the Western States, is astonished to learn that at the Freiberg smelting works in Germany, which treated but 70 tons of ore daily, complaint was made of the detrimental effect of smelter smoke, and the Government required sulphuric acid works to be erected at the expense of the smelter in order to get rid of the sulphur fumes. In the early experience of silver-lead smelting in the West, oxidized ores only were treated, and later when some roasted ore was added to the charge, the amount of sulphur was relatively small. The matte that was formed was heap-roasted and the smoke from the matte piles, practically containing sulphur dioxide only, caused little complaint. Sometimes the smoke would have a blighting effect when the wind was right for it, and the atmosphere was smoky to the leeward of the piles. Later, as the sulphide ores increased in quantity, they were roasted in hand or machine-rabbed reverberatories, and the fume was discharged from a stack, and thus became so diluted that it was not detrimental to vegetation. With the construction of large works treating thousands of tons of ore, the problem has greatly changed. The commonest ore of copper is chalcopyrite, which for proper self-roasting should contain (as much of it does) 25 to 35% sulphur. This is not the only drawback. At certain works not only is there sulphur dioxide, but arsenic, to contend with. While the latter cannot be called detrimental to vegetation, still it is poisonous if it falls in sufficient quantity upon vegetation which is to be used for forage. Again, the solid particles, or so-called flue-dust, falling upon the leaves of plants, may seriously injure them. The production of these substances is as follows:

In both lead and copper blast-furnaces the blast, coming up through the charge, makes a good deal of dust, and this in part settles in the flue that leads from the furnace to the stack. The velocity of the escaping gases is, however, too great to permit the settling of the finest particles. In the case of lead furnaces some lead is volatilized and upon cooling, a portion of it condenses upon the surfaces of the flue. The amount of SO_2 produced in lead smelting is not more than 0.2 to 0.5%. The fumes from a copper blast-furnace are different in constitution. They contain whatever arsenic has existed in the ore, and sulphur dioxide varying from 0.9 to 2.5%. (At the Washoe plant, Anaconda, it amounts to 1.5%.)

The fumes from roasters are largely SO_2 (up to 2.5%) produced by the burning of the ore, together with some dust caused (in the case of the McDougall roasters) by the fall of the ore from hearth to hearth, to the agitation due to the rabbles, and to the draft through the furnace. This dust settles in the flue leading to the stack.

In the case of reverberatory furnaces the charge is dropped upon the hearth in a body, so that comparatively little flue-dust is made. Some SO_2 develops as the result of certain reactions, indicated by the frothing or bubbling of the charge as it is melted. At the Washoe plant the percentage formed was 2.08 during the first ten minutes after charging. It drops to 1% during the succeeding 80 minutes of melting. Ebaugh gives the SO_2 as being but 0.01%, but this must be after the early reactions, and from furnaces where the charges are much more slowly treated.

The smoke, upon leaving the stack, is more or less dissipated according to the velocity of the wind. In still weather it rises rapidly and seems to be carried away at

a great elevation. With a moderate breeze it rises slantingly, but fills the air to leeward, while in a high wind part of the smoke will come to the ground at the base of the stack. And thus by this threefold action of the aerial forces, the upward-driving gases in calm, the buoyant but drifting smoke clouds in a moderate breeze, or finally the tumultuous energy of the gale tearing them apart, so that in any case they are dissipated and diffused through a mass of cubic miles of air, all contribute to act intermittently only upon a given area of the soil, so that relief comes to the harrassed vegetation, that it may make fresh effort to resist the next oncoming attack. It can be estimated that at one mile away, allowing 1.5% as being present in the escaping gases, the dilution (and not counting diffusion) will be such as to give 20 parts of the gas in a million of air.

Prof. Ebaugh has published an article in the Journal of the American Chemical Society, July, 1907, entitled 'Gases Against Solids, an Investigation of the Injurious Ingredients in Smelter Smoke' and thinks that "too much emphasis has been laid upon the injurious effect of SO_2 , and too little upon the harmful action of the solid constituents (flue-dust)." He finds the blighting action is greatest in wet weather, least in dry. The losses of crops are not total but partial, and vary from year to year.

Analyses made for SO_2 in the air at distances varying from one to seven miles from the smelting works showed no gas in 60% of some 500 cases examined:

60% contained.....	no gas
12 "	1 part of SO_2 in a million
20 "	2 to 3 " " " "
6 "	4 " 6 " " " "

leaving 2% of cases in which were found 7 to 10 parts of the gas in one million parts of air.

Upon passing air containing 1.5% of SO_2 over water to the point of saturation, the water at 90° F took up 0.33 volume of the gas per volume of water, and proportionately less as the air was weaker in gas. There is therefore but little chance of the gas when dissolved in water acting injuriously.

Hazellhoff and Lindau, German authorities, give the following conclusions regarding the action of SO_2 and SO_3 on plants:

- (1) No injury results to the soil nor to the roots of plants.
- (2) The gases act by contact on the leaves of plants, and analysis shows that the sulphuric acid content is greater than in smoke-free plants.
- (3) The sensitiveness of plants to such action varies with the species and with individuals which may show special immunity (white pines are susceptible, while post and white oaks and red maples are very resistant. Between these come black, red, and black-jack oaks and yellow and scrub pines.—Haywood).
- (4) Sulphur dioxide, even a few parts in a million, will, with long continued action, produce an injurious effect on vegetation. Commonly such action is intermittent and so, less harmful.
- (5) The gas acts by wilting the leaves, spots appearing and the leaves eventually turning brown or black and dying off. The SO_2 is probably converted to H_2SO_4 by the oxidizing effect of the leaves having thus a corrosive action upon them.
- (6) The action of the gas is more injurious by day than by night.
- (7) The action of the gas is cumulative, hence annual plants should be less injured.

In regard to the flue-dust itself, a sample of such dust, taken from the top of a stack, contained as follows: Moisture, 4.1%; SO_2 soluble in water, 17.7; total SO_3 , 33.9; Fe soluble in water, 3.6; total, Fe 16.7; Cu soluble

in water, 1.6; total Cu, 4.2; SiO_2 , 28.5; PbO , 8; As_2O_3 , 13; ZnO , 15%. This analysis indicates the presence of soluble and insoluble sulphates. Such flue-dust is hygroscopic, taking up water in a saturated atmosphere as follows: Original H_2O , 4.23%; after 12 hr., 10.21; after 24 hr., 12.05; after 48 hr., 13.09%. The corrosive power was roughly proportionate to the hygroscopic power. Dust, mixed with water, and sprayed upon sugar beets and alfalfa, showed severe corrosion. If, however, the dust was mixed with soil to the extent of 10% or less of dust, the corrosive action was small; with 20% dust in the soil the action was severe.

Thus the finely divided dust or fume from either copper or lead smelting works is extremely corrosive in its effects upon vegetation. Prof. Ebaugh finally concludes: "By no means is sulphur dioxide to be considered harmless, especially in an enclosed place and a moist climate, but we are forced, by the weight of evidence to the conclusion that heretofore undue influence has been laid upon the injurious effects of sulphur dioxide on growing plants, and that the solid emanations from the smelters, the so-called flue-dust, has been seriously under-estimated."

Haywood in an article entitled* 'Injury to Vegetation and Animal Life by Smelter Fumes,' says, in reference to the presence of arsenic at the Washoe plant, Anaconda: "Ores there treated contain in three instances As 0.51%; As 1.17%; and As 2.54 per cent."

He found upon the leaves of plants which were to be used for forage:

Bunch grass	2 miles north of smelter	78 parts As in a million.
Red top	4 " northeast " "	21 " " "
Bunch grass	3 " east " "	32 " " "
"	6 " west " "	42 " " "
Alfalfa	10 " northeast " "	52 " " "

This corresponds, on a ration of 20 lb. daily, to from 3 to 11 grains of arsenic. However, it does not follow that this amount of flue-dust *remains* upon the grass, since because it is soluble to the extent of 90% and upward, rains may remove it, and particularly in harvesting, because of the frequent handling in curing, hauling, and stacking, the larger part of the dust would be shaken off the hay before it was fed to the cattle.† We may conclude, therefore, that in those localities where smelters do injury, farmers should adopt the soiling or stall-feeding system.

The smelting companies have been compelled by the troubles they have had with farmers, to cast about for methods of avoiding these difficulties, and have worked out the problem in different ways. As I have elsewhere stated, the farmers may be divided into three classes:

First, those who do not feel they are damaged.

Second, those who honestly believe they are.

Finally, those who, while they do not believe it, make claims for the money there is in so doing. In Germany, for example, damages have been collected by cultivators, who have set out their grounds with expensive ornamental flowers unsuited to the climate, and which have no chance of prospering, in order to profit by damages for destruction by smoke.

The remedies that have been proposed may be thus enumerated:

(1) Manufacturing the SO_2 into sulphuric acid to be sold as an article of commerce.

(2) Operating the smelting works in a barren country where the fumes will do minimum damage.

(3) Roasting the ore where the country is barren, thus removing most of the sulphur (to 10% or less) from the

ore, then treating the roasted ore at a works convenient to labor and supplies.

(4) Roasting the ore at a works convenient to labor and supplies, discharging the resultant SO_2 by a high stack, then smelting the roasted ore, but filtering the fumes from this last operation by means of a bag-house.

(5) Filtering all fume resulting both from roasting and smelting.

(6) Introducing plants and animals best suited to withstanding the fume; adopting stall-feeding in place of grazing.

(1) This method may do well where there is a sufficient market for the sulphuric acid produced by the works. However, a large part of, say, 1,000 tons of ore daily would produce acid in excess of any probable demand. Besides this, only such SO_2 as was produced in roasting could be utilized, while the fume and flue-dust from the smelting would still do injury and would have to be filtered out.

(2) This was adopted at the Garfield plant of the American Smelter Securities Co., at Garfield, Utah, 18 miles from Salt Lake City. The land, especially in the path of the prevailing winds, was bought up by the company, which then proceeded to the erection of an expensive plant for the treatment of copper ore. The fume was removed by a stack the top of which is at a level some 600 ft. above the works. The fume is thus diluted before it can touch land beyond the acquired portion. In a way, the experiment has proved to be an expensive one, since the company has been obliged to build a town for housing the employees; and at this distance from Salt Lake City, it is hard to get good labor, as well as hard to keep it. It is true that the company obtains a profit from its investment in the houses and in its town, but this is not the line of business into which it had intended to go.

(3) This method has been proposed where there are existing works that, because of the large amount of sulphur fume produced, have been serious offenders. If the ore can be roasted near the mine, for example, where the land is not used in agriculture, the damage becomes comparatively trifling, and the work of roasting requires but little labor. The operations of smelting and of converting the product can then be conducted where supplies and skilled labor are available.

(4) Prof. Ebaugh's experiments go to show that SO_2 gas alone may not cause radical injuries to plants and certainly not to animals, provided it is free from flue-dust. Indeed, according to Merrill's experiments* in the smelter zone, with stock properly fed and cared for, the animals flourish quite as well as elsewhere. If then the SO_2 gas from the roasters is allowed to escape freely into the air, it means that the main bulk of gases is thus disposed of. An ore containing 30% sulphur can thus be reduced to 7%. If we smelt and convert this roasted ore, we may easily filter the small volume now remaining to be handled as referred to in method No. 3.

(5) At the American Zinc Works, near Canyon City, Colorado, the company has for years filtered all the gases from their roasters and blast-furnaces, the latter being purposely run to make all the zinc and lead fume possible. These gases are first cooled to the proper temperature, both by passing through sheet-metal flues and by the admixture of fresh air, then having been filtered at the bag-house, there is no smoke visible. This is also true of the bag-house installed in connection with lead-smelting plants. Where works thus provided deliver visible smoke, it is that coming from the roaster-stack. Even this can be filtered, but it is a more difficult problem, the bag-house needing to be fitted with the more expensive

woolen bags, which stand the attack of the corrosive sulphates and sulphuric acid, and small as is the quantity of them produced, cotton bags would be readily corroded. Still, even in large works, all the fumes can be filtered. By so doing, not only the flue-dust but the arsenic can be got rid of. The flue-dust collected in the 'pits' at the bottom of the house contain a large percentage of arsenic, and such flue-dust is to be sent away where it may be safely treated, or the whole product buried, thrown into an abandoned shaft, or otherwise got rid of.

(6) It has already been shown that there is a great difference in the resistant power of plants to the fumes, and this power varies both with species and with individuals. Especially where the land is owned or can be controlled by the offending smelting company, it should be good policy to plant those species of trees most resistant to the smoke. Forage plants should be selected in the same way and cattle should be stall-fed, rather than be permitted to pasture upon them. Root-crops, as sugar-beets, should be raised, since while the leaves of these plants may be damaged, it will not be to the extent of preventing a profitable growth of the plant. As far as the forage plants are concerned, the damage to the leaves varies, and is often so slight as to make little difference in the value of the plant for fodder.

In conclusion, we may consider the findings of the Master in Chancery, Oliver Crane, to whom was referred the matter of damages due to smelter smoke from the

on a site where it will do less damage than any other available place, and that the company has always been willing to pay some damages.

FLORIDA continues to be the largest producer of phosphate rock in the United States. The output of the State for 1906 was 1,304,505 long tons, valued at \$5,585,578,

Cross-section of Main Flue at Anaconda.

against 1,194,106 long tons, valued at \$4,251,845, in 1905, and the percentage of the total production increased from 61.3% in 1905 to 62.4% in 1906, notwithstanding that the

Repairing the Big Flue of the Washoe Smelter, June 4, 1907.

Washoe plant. He finds that the farmers had been somewhat damaged by the arsenic, but not by the SO_2 contained in the smoke. He says that an injunction and the closing of the smelters would damage the farmers and the community more than a continuance of the nuisance complained of; that the company had been doing what it could to avoid damages, and that the smelter is built

year was a wet one and much trouble was experienced in the mines owing to the high ground-water level. The increase was confined to the hard rock and the land pebble, which increased in price respectively from \$5.18 and \$1.98 per long ton in 1905 to \$5.85 and \$3 per long ton in 1906. There was a falling off of more than 50% in the production of river pebble.

The Possibilities and Limitations of Geological Survey Work as Applied to the Mining Industry.

By GEORGE OTIS SMITH, Director of the United States Geological Survey.

*The year 1907 promises to mark an epoch in the mining industry of the United States. I refer to the probability that the value of the mineral output for this year will pass the two billion dollar mark. Last year was a record-breaker, with its mineral product valued at over \$1,902,000,000, an increase of 17% over the output of the previous year. Therefore, before I discuss the relation of the Geological Survey to the mineral industry, allow me to call your attention to the fact that in the first year of the Survey's history the value of the mineral product of the country, so far as known, was only about one-ninth of the present figure, and further, that now the value of the annual product of our coal mines alone exceeds one-half billion dollars, or, in other words, is more than twice the total value of all the mineral products in 1880. At this time we do well to consider whether this Federal organization has had any part in the national progress, and whether it intends to keep pace with the development of your industry, a development it has carefully recorded during these 28 years.

In any review of the development of American mining, the man behind the pick and the drill must be given his due; but motive power counts for little without knowledge to guide it. And I take it that the American Mining Congress stands for the intelligent guidance of the mining industry, and in this the United States Geological Survey heartily joins you.

In speaking to the subject assigned me, I ask for the Survey a fair recognition for its part in the past of American mining, and I promise for the Survey even greater endeavor to increase its usefulness to your industry in the future. In making this promise of future service I am conscious of the two fundamental limitations of a Government organization; the United States Geological Survey is the servant of the people along lines defined by the law of Congress, and both the direction of our progress and the distance covered are determined and limited by the appropriation act.

Limitation is but another name for boundary. What then are the boundaries of our field endeavor? Or, if you please, the endlines of our claim? Interested as I am in future development of the organization I represent, I believe we should not be asked to surrender extra-lateral rights, but only to show the persistence of the lode to justify further expansion of the work.

Congress has expressed the scope and purpose of this branch of the public service in its name. The words "United States" define its national character. In no branch of industry, probably, are State lines of so little moment as in the mining industry. A mineral product of fifty years ago might have been credited to a single State; but, today, by reason of development of transportation, with its influence upon financial operation and commercial interchange, the output of our mines and quarries not only reaches the markets of the world, but in many cases the marketed product is of interstate origin. Years ago a shipment of pig iron could be set down as the product of a Marquette county furnace using Michigan iron ore from the mines close at hand and Michigan limestone as well as charcoal from the neighboring hills; today, the blast-furnace in eastern Pennsylvania may use Minnesota ore, West Virginia coke, and

New Jersey limestone, and ship its product to California. Nor is the case at all different in the smelting of ores of the precious or other metals. Our smelters, whether in the East or the West, levy tribute upon the mineral wealth of many States and rarely can the best mixture of ores be obtained from a single State. Again, in the study of ore deposits the mining geologist, who, for instance, can continue his investigations year by year through a series of copper camps, has a great advantage over an investigator whose observations must be confined to the mines of a single State. This increase in opportunity means increase in value of results secured and published for the information of the public.

The collection of mineral statistics and the study of mineral deposits, then, must of necessity be made by an organization whose field is the whole country. As regards authority, the first Director of the Survey, Clarence King, well remarked that the constitutional right of the Federal Government "to regulate internal commerce could hardly fail to carry with it the correlative right to gain a knowledge of those commodities and products which are the very material and basis of commerce." In its relation to the mining industry, therefore, I discover no limitation set upon the work of our Survey by reason of its federal character; but rather see in this one of its greatest sources of strength and efficiency.

The second part of the name is "Geological." In the wording of the law creating the Survey, "mineral resources" and "geological structure" are linked together in a closeness of union that is well justified by the results of investigations showing the absolute dependence of the one upon the other in so many mining districts. There is, then, a fitness in the use of this adjective "geological" in the title of the organization. It expresses a recognition of the real basis of the mining industry, and upon this foundation the Survey has built well.

Between the lines of every appropriation bill for work under the auspices of our Survey we may read the words 'practical' and 'utilitarian'; yet even this evident purpose of the appropriation is not to be considered as a limitation upon the nature of the work. The very name of the organization to which these funds are entrusted speaks for its scientific character and in science progress is not attained by the separation of the practical from the theoretical, but by their union and co-ordination. The fruitage of theory is practice and we cannot gather the harvest without carefully tending the tree of knowledge. It is most important not to limit our concept of the useful as did the Englishman, who is quoted by Huxley as understanding utility to mean "that by which we get pudding or praise, or both." Better to count every investigation useful which our faith tells us may some time win pudding and praise for the other fellow. On this account you practical men must not underrate the contribution of the worker in pure science, but rather realize that his work is fundamental. For these reasons, again, we count it not a limitation, but the greatest advantage that this Federal organization approaches your important industry from the scientific side.

In the third place, I can discover no embarrassing property line in the word "Survey." To most of us, does not the term carry with it the flavor of the West, and the inspiration of discovery and exploration? It expresses the idea of getting at the truth at first hand, while such a word as 'bureau' serves only to emphasize the administrative and clerical side. "Survey," then, stands for work in the field, the winning of truth, not from books but from rocks, not in the office but in the stope; and, as you men well know, it is upon thorough field investigation alone that you can rely. On this account, I rejoice that 28 years ago Congress, in its

*An address delivered before the American Mining Congress, at Joplin, on November 11.

wisdom, retained the use of this one word which links the present organization with its predecessors whose records in the winning of the West are a valued heritage.

Our title to the claim is well established, for our patent rests upon no nominal compliance with the requirements as to assessment work. The field in which you are interested is a broad one and you are justified in the statement that too little attention has been given to your industry by the Federal Government. Yet, thus far all the development work is to be credited to the United States Geological Survey, and many witnesses could be cited to prove the value of its output. The subject of mining geology was put foremost in the plan of the organization of the Survey and the impetus then given to the investigation of ore deposits continues to the present day. Dr. Raymond, the Secretary of the American Institute of Mining Engineers, has said that the leadership which American observers have taken in the science of ore deposits must be attributed not only to the rich field here afforded and its active development by mining, as well as to the liberal expenditures made by State and Federal governments for its study, but also to what is most important, namely, the presence of men competent to take advantage of these favorable conditions and "the wise provision made for such investigations by the first Director of the United States Geological Survey."

May I now speak of the possibilities of the Geological Survey? At other sessions of this Congress representatives of the Survey have explained to you the contributions it has made to your industry, and already I have incidentally touched upon the same subject. I propose, therefore, to confine myself to only a brief mention of the present work, and that merely as a basis for the statements of further possibilities of development.

Our topographic maps, in accuracy of detail and in excellence of mechanical execution, are of the highest grade. Every three days our office is publishing one of these maps based on actual survey, and much oftener is printing a new edition of some earlier sheet; yet we appreciate the fact that one class of men, to whom many of these maps would be of greatest assistance—the prospector—rarely knows that such a map is extant. Of even greater value is this map to the mine operator, who follows the prospector and plans the development of the property, and therefore should have before him all the data bearing upon the important questions of water supply and transportation. The endeavor of the Survey must be, not alone to make better topographic maps and more of them, but to get these maps into the hands of the people for whom they are made.

Much the same statement can be presented regarding our geological maps. Every month, on the average, a folio is issued which presents graphically all that is known regarding the geological structure and the distribution of the mineral wealth within a district embracing an area of from 200 to 1,000 square miles. A large proportion of these geological folios cover mining districts and are especially addressed to the mining fraternity. However, it again appears that the Survey's geologic folios do not reach all who might profit by the facts they set forth. The price asked for these publications is only nominal, the real difficulty is that of advertising our output. Recognizing the possibility of increasing our usefulness by wider publicity, I pledge myself to a special effort to reach the mining man, however distant from the great centres he may be.

Perhaps the Survey has nowhere better improved its opportunity to aid the mining industry than in Alaska. The literature on Alaska of value to the mining man is almost wholly composed of Survey publications; yet the exploration work represented by these reports and maps

has involved an expenditure of less than \$500,000, or only one-half of 1% of the gold output for the same period. Few taxes are so light as this, especially when we consider also that the work done by the Government geologist covers also the coal, copper, and other resources of that region, and that the benefits will continue through a term of years.

Reference has already been made to the importance of reliable statistics regarding the mining industry. At the time of the organization of the Geological Survey the country possessed no adequate knowledge of the status of mining, although this is one of the great primary industries based upon natural resources. Advantage was at once taken of the new organization, and the systematic statistical study of the mining industry under the 10th Census was entrusted to the Director—Clarence King. I refer to this because in the successful issue of the work under these auspices can be discerned the correct policy for this important work. King's plan of utilizing for statistical work the services of those most closely in touch with the mines deserves continuance, and in view of our recent progress along this same line I assure you that there is within our reach the possibility of much greater usefulness to your industry.

The scope of the Survey's statistical work, like that of all other of its investigations, has been limited by the appropriation available; increase that, and more and more can be done in the matter of keeping the country informed as to the phenomenal development in the technology of the mining industry as well as the no less marked increase in production. I need only to suggest to you the inherent connection existing between an adequate and exact knowledge of any industry and its future development. It is only by observing, recording, and publishing each advance in the utilization of these mineral resources that true progress will be insured; and here, again, it is to be noted that to secure the best results there must be the closest relations between geologist and statistician; best of all is it when the investigator can justly claim both titles. Without full information regarding the latest development in mining, metallurgical, or milling practice, the geologist-explorer cannot intelligently conduct the work entrusted to him, and on the other hand, without a quantitative knowledge of the varied contents of nature's mineral storehouse, the student of statistics cannot appreciate the bearing of the data he collects.

The record of the Geological Survey in mining geology warrants the hope of greater development in the field it has occupied during these years. Let me again cite the disinterested testimony of those unconnected with the organization. A leading mining journal has within a few years stated that in no other country "has economic geology been applied to the development of industry with such beneficent results as in the United States, and no (other) geological survey has contributed so much to the practical application of the science of geology to mining operations."

Not only in this country, but abroad, the United States Geological Survey is regarded as in reality performing the work of a mining bureau by reason of its activity in fostering the development of the mineral resources of the country. Last year, the *Canadian Mining Review*, in an editorial, pointed to the successful contributions to the mining industry made by our Federal Survey as the strongest argument against the continuance of the independent existence in Canada of a Geological Survey and a Mines Branch, with the resultant duplication of endeavor involving greater expense and less efficiency. The effort should be, not only to expand the work, but also to seek a logical correlation of all the various

branches of research that will benefit your industry, for logical correlation means economy.

I must not leave the subject of mining geology without a reference to one of the greater possibilities for increasing the efficiency of the Geological Survey. Legislative authority should be secured for a certain amount of investigation in foreign countries of ore deposits, together with mining conditions and methods. Several of the Survey's mining geologists, from time to time, while on leave of absence, have been engaged by foreign corporations to report upon properties in South Africa, Australia, and South America, and the extent to which the Survey has benefited by reason of their foreign service is keenly appreciated.

The statement of official publications planned by the first Director of the Geological Survey indicates the value which he attached to investigations into the technology of the mineral industry, even to the matter of testing the relative cost and efficiency of different types of mining and milling machinery. Little, however, was done along these lines until, under Mr. Walcott, the Survey took up the fuel-testing work which has reached so successful a development under the recently organized Technologic Branch of the Survey. The chief of that branch has already addressed you on the need of conserving our mineral resources, and I need add little to his argument for increasing our work for the better utilization of fuels and the prevention of waste.

Again, I wish to call your attention to the complexity of the mineral industry of today. The inter-dependence of the one mineral product upon many others makes the miner of all men dependent upon many factors outside his own mine. Waste of our supply of wood, water, and mineral fuels will hasten the day when certain ore deposits can no longer be mined at a profit. Hence, we count upon you mine-owners for hearty support in the work that the Forrest Service and the Geological Survey are doing in the conservation of the natural resources of the nation.

At the El Paso session of this congress the Chief Geologist of the Survey enumerated certain apparent needs of the mining industry for meeting which insufficient provision had been made by the Federal Government. The arguments clearly set forth at that time I will not repeat, yet it is worthy of note that a full compliance with the demand for free assays and for free advice, both as regards mineral properties and mining technology, would be of the nature of an expansion of work already undertaken by the Survey.

One distinction, however, must be made between what may be asked and what can be granted by the Geological Survey. I refer to the legal restrictions by which "the Director and members of the Geological Survey shall have no personal or private interests in the lands or mineral wealth of the region under survey, and shall execute no surveys or examinations for private parties or corporations." This law may be thought to restrict our activity somewhat, yet it surely adds to the value of our results. Increased appropriations would enable us to meet these specific needs, although the assays and other examinations made by the Geological Survey should be only for new finds, or for new methods, and the results should be promptly published for the information of the public rather than of the individual. In a word, the work of the Survey geologist, engineer, statistician, or chemist is planned not to encroach upon that of the mining engineer or the assayer in private practice, but to be basal in character, and of a nature to assist these professional men as well as the prospector and the mine-owner. I am not unmindful of what your industry has suffered at the hands of the unscrupulous, who masquerade under

the title of expert, and against these the Federal survey is ready to protect both prospector and investor. More and more is our organization taking upon itself work of this kind, which is always delicate and often thankless.

It may be well to note that the Geological Survey is not charged with the enforcement of the law, but is rather a bureau of information; yet as such it is no less our duty to assist in law enforcement, especially in all that relates to the classification of the public lands. At the time of the inauguration of the work of the Geological Survey the classification intended by Congress was believed to be general in character, and such as would be expressed upon maps issued for the general information of the people. The present interpretation is that the classification should be more definite, and, therefore, during the past season the Survey has been actively engaged in the classification and valuation of the coal land of the public domain. Increased demands are also being made upon our mining geologists for assistance in the determination of the mineral or non-mineral character of land of which title from the Government is sought. In all this work the sole purpose of the Geological Survey is to determine the truth of the issue and thus to protect the interests of the public. Our purpose is to assist the legitimate miner by opposing his worst enemies, the land grabber and the unscrupulous promoter of wildcat schemes, and in this we know that we have the support of the men who really represent the mining industry.

Your president has outlined definite recommendations for the further extension of Federal work in aid of the industry you represent. With full faith in the trained men who constitute its working corps, I promise, in behalf of the Geological Survey, that our possibilities in your service will be limited only by the appropriations which your representatives in Congress may entrust to us. In the Survey's effort to serve the mining industry, then, I recognize no limitation beyond those set down by Congressional enactment, and I will gladly join with you in the effort to seek to make such enactment fit your real needs. Under what Federal auspices the mining work should be conducted is not so important a consideration as that the work should be done and done well.

In conclusion, the lines along which I propose to have the United States Geological Survey advance to a position of greater usefulness to the mining industry are these:

First—The fuller recognition of its duty in the classification of the mineral lands of the public domain.

Second—The rapid extension of systematic field study of all mineral deposits, so that geological exploration may keep in advance of economic development.

Third—The further development of the Survey as a source of authoritative and disinterested information, for the benefit of the prospector or the land owner.

Fourth—The broadening and improvement of the methods of collecting mineral statistics, with the purpose of securing more accurate returns and of expediting their compilation and publication.

Fifth—The investigation of processes relating to the mining and later treatment of fuels, ores, and other mineral products, in so far as such investigation may be fundamental to the best utilization of the nation's mineral wealth.

Sixth—The preparation of reports that will better meet the needs of the mining industry, and the distribution of publications more promptly and effectually.

These are not radical departures, for the Survey is at present making progress along each of these lines of public service, and we mean to continue that progress; yet the rate of our advance, and that is what you are most interested in, will be largely accelerated by the more generous support which you are able to ask for us.

History of Cyanidation.

By PHILIP ARGALL.

*About two hundred years ago the chance manipulation of impure chemicals by Diesbach, a Berlin color manufacturer, resulted in the formation of ferric ferrocyanide or prussian blue—the first cyanogen compound known. This chance discovery of a new compound and a new color, while of the first importance to Diesbach, was none the less portentous of the yet undiscovered cyanide compounds which have since revolutionized more than one industry, and added mightily to the gold production of the world.

The simple production of prussian blue was distinctly epoch-making, and rightly takes rank amongst the greatest of chemical discoveries, if measured only by the present usefulness of the cyanogen compounds in the metallurgy of gold. At the time prussian blue was discovered in 1704 indigo was the only blue coloring matter known, and so we find Diesbach and his partner, Dippel, an alchemist, were quite early engaged in the manufacture of this new and beautiful cyanogen compound. In 1710 Dippel presented a paper to the Academy of Berlin calling attention to the new compound, without, however, disclosing the method of its preparation. Fourteen years later Woodward¹, an English chemist and Fellow of the Royal Society, not only succeeded in making prussian blue, but also made public the method of its preparation, and it is interesting to note that this method of Woodward's is practically the process by which prussian blue is prepared today. Macquer, in 1752, observed that when prussian blue is boiled with caustic potash, oxide of iron remains, whilst a peculiar salt enters into solution which was named phlogisticated alkali, or yellow prussiate of potash². This body was shown to contain iron and prussic acid by Berthollet in 1787.

The actual composition of prussian blue was not known until 1782, when Scheele, 78 years after its discovery, obtained an acid from it which, in consequence he named "prussic acid," but even then the composition of the acid was not known. Prussic acid, hydrocyanic acid, or nitride of formic acid (CNH) occurs in certain plants, as for example, in laurel leaves, peach leaves, and in kernels of several kinds of stone fruit. The acid, however, was first obtained in the pure state by Gay Lussac³ in 1811, while four years later the same chemist discovered the radical cyanogen and showed that it was capable of existing in the free state. Hydrocyanic acid is said to have been known to the Egyptian priests and used by them to kill traitors.

Cyanide of potassium was first made by the simple fusion of yellow prussiate of potash and ferrocyanide of potassium in iron crucibles; when this operation is properly conducted the result is a mixture of carbide of iron and cyanide of potassium, the former adhering to the sides of the crucible, the latter in the midst of the mass. With a view to remedying certain objections to the foregoing process, Liebig proposed the ignition of dry ferrocyanide in the presence of dry potassium carbonate. At present much of the cyanide of potassium used in cyanidation of ores is produced by the Erlenmeyer process, which is based upon the action of sodium on ferrocyanide of potassium according to the reaction:

The resulting product is next treated with water, the solution evaporated, and the salt sold as 98% potassium cyanide, but it is really a mixture of 1 molecule of potassium cyanide and 2 molecules of sodium cyanide.

With the introduction of the aniline colors, prussian blue found but a limited use in the arts, while cyanide, formerly of limited application in medicine, photography, electroplating, and as a laboratory reagent, has, since the cyanide process was established on a full scale, been used in greater quantities than any of the cyanide compounds, even now over one-half the potassium ferrocyanide produced is used in the manufacture of potassium cyanide.

Cyanogen, really a nitride of carbon, greatly resembles the halogens, and in many reactions behaves like a simple substance, or in other words, plays the part of an element. The radical cyanogen combines like chlorine with hydrogen and the metals; its compounds are comparable with those of chlorine, to which they have the strongest resemblances. Therefore as the halogens, chlorine, bromine, and iodine all dissolve gold, as do also some of their compounds, it was but a natural inference that cyanide of potassium would dissolve gold, as pointed out by Hagen in 1806. Of the various cyanogen compounds, I shall now confine myself to potassium cyanide (KCN) and endeavor to show in a casual way the development of this salt as a gold solvent on a practical scale.

It is reported that Dr. Wright, of Birmingham, England, used gold cyanide solutions for electroplating as early as 1840, in consequence of his investigations following the publication of Scheele's report on the solubility of gold cyanide in a solution of potassium cyanide. The brothers J. R. and H. Elkington made the first practical application of potassic cyanide as a gold solvent, and patented it in 1840, in connection with the electro-deposition of gold from cyanide solutions, or at least the first application I have been able to find, though it does look somewhat closely related to Dr. Wright's process above mentioned.

The Elkington solution was made by dissolving salts of gold in potassium cyanide; in their arrangement the articles to be gilded form a cathode, a plate of gold the anode, both immersed in the cyanide bath. The gold as deposited on the article to be gilded was dissolved from the gold anode plate, thus keeping the auro-potassic cyanide bath of about the same strength; here we see that a solution of potassium cyanide, plus electricity, was at this early date (1840) a known and recognized commercial gold solvent, and with but slight modifications it is so used in electroplating today.

In 1843 the Russian Prince Bagration⁴, while investigating the Elkingtons' process, discovered that cyanide can dissolve gold without the aid of electricity. It is said that in the course of his researches he poured some cyanide solution into a gilded vessel and on emptying the vessel sometime later found the gold plating had been removed from the sides and bottom. After a thorough examination Bagration reached the following conclusion, which not only stands good today but also quite fairly sums up our general knowledge of the action of potassium cyanide on gold:

First, that cyanide of potassium will dissolve metallic gold; second, that if the gold is very fine it will pass rapidly into solution; third, that the electric current did not in the least help the solvent action of the solution of the gold; fourth, that heat greatly assisted the solution of the gold; that gold in cyanide solution can be precipitated on metallic surfaces without the aid of electricity; and lastly, that the air has a very marked action in quickening the solution of gold in cyanide solutions.

We next come to Elsner⁵, who in 1841 stated as the result of his researches:

"The dissolution of the metals (gold and silver) is, however, the consequence of the action of oxygen, which,

*A paper read before the Colorado Scientific Society on November 2, 1907.

absorbed from the air, decomposes part of the cyanide."

This statement, showing oxygen to be necessary, is probably the most important fact connected with the use of cyanide as a gold solvent, and is rightly claimed as the second step in the dissolution of gold by means of potassic cyanide. The recent development of the cyanide process is the direct outcome of this theory. It should be noticed, however, that Elsner's work at this time was merely qualitative: that he did not even suggest an equation to show the possible reactions involved in the solution of the gold, and that the much quoted Elsner equation was only given to the world during an inaugural dissertation at Göttingen 22 years later (1866). In 1857 Faraday pointed out⁶ that gold leaf resting on the surface of a cyanide solution dissolves a hundred times quicker than gold leaf that is only immersed therein. Faraday believed that air voltaic currents are formed in these cases, and that the gold is dissolved almost entirely under their influences. This appears doubtful.

Up to this time strong solutions of cyanide were used. In 1866, however, Dr. Henry Wurtz⁷, in the *American Journal of Science*, made the important announcement that weak solution of cyanide would dissolve gold. In the following year J. H. Rae⁸ of Syracuse, N. Y., patented an important method for treating gold and silver ores; by subjecting them to a cyanide solution and an electric current, following by precipitation on copper; also by electricity. Rae then, as far as our knowledge goes, made the first application of cyanide to ore treatment, and used agitation to hasten the action. It is very doubtful, however, if this patent was even put into even experimental use on a working scale. I pass over the inventions of Thomas C. Clark of Oakland, California⁹, Hiram W. Faucett of St. Louis¹⁰, and John F. Saunders of Utah¹¹ as immaterial, though cyanides were used by them or claimed to be used under the patents applied for, yet their processes do not bear the stamp of practicability, and have long since been forgotten. They do, however, show that the minds of American inventors were running towards cyanide—scenting, as it were, the coming battle from afar.

The next inventor to hold the field is Simpson of Newark, New Jersey¹², who patented, in 1885, a process for separating gold and silver from their ores by means of subjecting the ore to the action of a solution of potassium cyanide and carbonate of ammonia, precipitating on zinc, which he does not, even at that date, claim as new. Simpson's great improvements are, therefore, the introduction of an alkali to correct acidity, dissolving the precious metals without electricity; and also precipitating without an electric current. Simpson's patent covered the ground very fairly, but it was not pushed; was, in fact, one of those great inventions that lie dormant for years, as if they had arrived before their time. It may be, however, that suitable ores were not available for Simpson, for we hardly believe that had the Mercur (Utah) ores, or those of Johannesburg been available, Simpson's process would, notwithstanding the then very high price of cyanide, not have been developed into a commercial success.

These American patents of Rae and Simpson attracted notice abroad, for we find W. A. Dixon, in a lecture before the Royal Society of New South Wales, in 1887, going somewhat out of his way to decry an American gold extraction process in which potassium cyanide was the solvent. His principal objections were the cost of the salt used, its instability and poisonous nature, quite per-

tinent, and not unreasonable criticism at that early date; indeed, within the present year I have had almost precisely similar criticism leveled at a slight departure from the beaten path of cyaniding that I had intended taking, in which it was proposed that the ore be crushed, concentrated and agitated in dilute cyanide solution. W. Skey, the distinguished New Zealand chemist, called attention in 1875 to the fact that both gold and silver were soluble in cyanide solutions, and that considerable losses of precious metals occurred in amalgamation mills from the too free use of cyanide.¹³

From 1886 onward many chemists were at work on various cyanide schemes, none of which cut much figure until MacArthur and Forrest, of Glasgow,[†] secured their patents in 1887, and formed the basis of a successful working process, introduced by the Cassell Gold Extraction Co., but for some reason it was not applied on a working scale until 1889, when a plant was erected at the New Zealand Crown mines, in the Karangahake district. Here agitation formed a prominent feature of the process, but later was replaced by the percolation methods. The ores of Karangahake are very difficult to treat by the old methods; battery and amalgamated copper plate gave only some 15 to 20% extraction; dry crushing and pan amalgamation gave about 60%, while cyanide yielded 90% of the assay value of the ore. The following year, 1890, the tailing from the Robinson mine, at Johannesburg, South Africa, was successfully cyanided, and from that date it may be said the process sprang into general use all over the world.

I have traced quite briefly the various stages leading up to the introduction of the cyanide process on a commercial scale, and we might now ask who invented the process? Like most other achievements, no one can lay full claim to its entire invention; in fact, it was not invented, but grew in the minds of men, until the fullness of time and a suitable ore had arrived, and then success could not be prevented. Let us glance briefly at the MacArthur-Forrest patents, and their reception by the courts, to see whom the law decided to be the inventor of the process:

The first patent, No. 14,174, the MacArthur-Forrest,¹⁴ was taken out in England, October 19, 1887, the specific claim being:

"1. The process of obtaining gold and silver from ores and other compounds, consisting in dissolving them out by treating the powdered ore or compound with a solution containing cyanogen, or cyanide, or cyanogen-yielding substance, substantially as heretofore described.

"2. The process of obtaining gold and silver from ores and other compounds, consisting in dissolving them out by treating the powdered ore or compound with a dilute solution containing a quantity of cyanogen or a cyanide or cyanogen-yielding substance, the cyanogen of which is proportioned to the gold or silver, or gold and silver, substantially as hereinbefore described."

In describing the method of separating the precious metals from solution, the patent states the solution is treated "in any suitable known way, as for example with zinc." Thus showing that in August, 1888, zinc precipitation was, in the opinion of the patentees, a suitable known method, and hence not claimed in the patent specification.

Coming now to the American patents of MacArthur and Forrest: The main patent is dated May 14, 1889, No. 403,202, the specific claim being¹⁵: "Subjecting the powdered ore to the action of a cyanide solution contain-

ing cyanogen in the proportion not exceeding eight parts of cyanogen in one thousand parts of water." In explaining their process the patentees state the invention consists in subjecting the auriferous ores to the action of a solution containing a small quantity of cyanide—without any other chemically active agent.

The next American patent¹⁶ is 418,138, issued December 24, 1889. It relates to the filiform zinc sponge for precipitating the gold from cyanide solutions, now almost universally used for that purpose, though just as satisfactory results can often be obtained by the use of zinc powder. This method, however, was the subject of a British patent issued to Astley P. Price¹⁷ in 1884, which clearly anticipated the use of zinc as provided for in the MacArthur-Forrest process; nevertheless, the filiform zinc is in my opinion preferable, and it was both a new and novel form of precipitation, and as such worthy of an enforceable patent. These various MacArthur-Forrest patents were taken out in the principal mining countries throughout the world.

The German patent was cancelled February 2, 1895, by decree of the Imperial German Court, based chiefly on priority of invention by Rae and Simpson in America.¹⁸

As to the exclusive use of cyanide by MacArthur against cyanide and carbonate of ammonia by Simpson, the Court said:

"If the additions used by Simpson are, however, substantially immaterial for the purpose aimed at, then ammonia is certainly a simplification of the process, but not an alteration affecting the essence of the same. Furthermore, too, the monetary value of the addition is such a trifling one that the saying cannot be considered as industrial advance."

The second trial of the patent was conducted in England, in November, 1894, before Mr. Justice Romer, a gentleman as widely known by his scientific attainments as by his legal learning. His decision goes over the ground of the Rae and Simpson patents, and the chemical knowledge universally known that cyanide was a solvent for gold, and states:¹⁹

"But in addition to the above, I think there is another ground on which this patent is bad. Even if the invention was one which could form the good subject of the patent, I think it was anticipated by Rae's and Simpson's specifications. Test it in this way: If the patent were held valid, would not Rae's and Simpson's processes, if now used according to the specifications published, be liable to be stopped as infringements? I think they certainly would. What chance of escape would a person have who took Rae's, for instance, and used the cyanide of potassium specially mentioned by Rae? It would be used against that person with crushing effect, that he was using the cyanide of potassium for the very purpose pointed out in the plaintiff's patent, namely, to dissolve the gold in the crushed ore, and not the less because he tried to assist the process by the aid of electricity, which might or might not be of any real assistance, and certainly not the less because he used the electricity for another and different purpose. So, also, a person using Simpson's process would be liable to be stopped. For it would be proved against him that he was using the cyanide of potassium for the very purpose and in the very way pointed out in the plaintiff's specification, and that the addition of carbonate of ammonia made no material difference. To hold that Simpson's was not an anticipation would lead to a strange result. A person using cyanide of potassium

alone would be an infringer, but, if he chose to add a slight amount of carbonate of ammonia (which is cheap and practically innocuous), he could not be restrained. Now, as the specifications of Rae and Simpson were published here before the date of the plaintiff's patent, all persons in this country are at liberty to use the processes there set forth, and that right is incompatible with those persons being liable, if they do use such process, to an injunction at the suit of the plaintiffs. For these reasons the action must be dismissed."

The decision of Justice Romer was reversed on appeal, or partly so, and in amending the patent to conform to the American claims, it became binding in England.

The Transvaal patent was the most valuable of the MacArthur-Forrest Co., and on it the most stubborn fight was made. Here again the selective action of weak solutions constituted the principal claim of the defendant company. The patent appeared to be similar to the English one, the first claim for the MacArthur-Forrest process being a discovery that a solution containing cyanogen would dissolve gold. The second, being less general, stated that a dilute solution of cyanide proportioned to the quantity of gold had to be employed.

Judgment of the full court follows:

"The plaintiff maintains that this so-called MacArthur-Forrest process is not a new discovery, and has been anticipated. With regard to the first claim, that a cyanide solution dissolves out gold from ore, we may take it as clearly established by the evidence that at the time when the patent was applied for and granted it was a well known fact that gold could be obtained from ore by a solution of potassic cyanide. The first claim, therefore, in favor of the MacArthur-Forrest patent, No. 47, cannot be sustained."²⁰

In this case counsel argued strongly that MacArthur and Forrest showed that weak solution of cyanide dissolved gold, and had, as they claimed, a selective action for gold over the base metals in the ore. On this point the Court said:

"Chemical affinity is, however, a law of chemistry, a law of nature, which, as Mr. Wessels argued, can no more be patented than the law of gravitation."

The mere dilution of a chemical was held to be no invention. The patent was cancelled. Adverse decisions were also given in New Zealand and several of the Australian colonies.

Returning to the American patent: Pure cyanide solutions, without the aid of any other active chemical, will not dissolve gold. Oxygen is necessary, and this point alone would probably have invalidated the American patent, as the patentees limited themselves to cyanide alone, excluding the very active agent oxygen.²¹

(To be Continued.)

RAILWAY CONSTRUCTION IN PERU.—London financial journals report that a settlement has been reached in the long outstanding dispute between the Government of Peru and the Peruvian Corporation, the latter being the company that operates almost the entire railway system of the country. New contracts are to be made with respect to the works at the port of Mollendo in the south, and in regard to Chira canal in the north. The corporation is to complete the railway extensions from Oroya to Huancayo, from Sicuani to Cuzco, and from Yonan to Chilite, such extensions to be ready for provisional traffic by September 24, 1908, and to be definitely completed nine months later. The lease to the corporation is to be extended 17 years, during which period the Government is to receive 50% of the net profits of the railways.

Sliming Ore for Cyanidation.

Written for the MINING AND SCIENTIFIC PRESS
By MARK R. LAMB.

The numerous recent attempts to treat any and all ores as "all slime" have resulted in much valuable information. It is not so certain from the present outlook that the sliming of all the ore is generally advisable or even possible. It will be remembered that Mr. E. M. Hamilton brought this out plainly in his report on El Oro ores. However, the recent great improvement in slime-filtration seems to be responsible for the prevailing opinion that it is possible, even easier, to treat and wash sand by agitation and vacuum-filtration than by leaching. As is usually the case in metallurgy, there is a happy medium method and the recent partial failures seem to have pointed this out. It is necessary to premise such a note as this with the clear statement that no two ores are mechanically alike—that in all cases individual experiments must be made. With this understood, it is safe to say that sand cannot always be filtered successfully on vacuum-filters.

One plant was designed and erected along these lines after careful and repeated tests (not mechanical) and it now transpires that although extraction from the finely ground ore is rapid and all that can be desired, it is practically impossible to agitate with geared stirrers if the pulp is once allowed to settle. Further, it is practically impossible to keep the pulp in suspension during filtration. The ore is largely hematite and while a part grinds almost to a solution, being very difficult to filter, another part remains as a very heavy sand, settling like shot and packing like cement. This problem is to be solved by air-lift agitation and subsequent classification. The separated sand will be washed in a comparatively small leaching plant. This classification will be simple and allows of a leaching rate of about three inches per hour.

Set off against this plant and its results, the recent experiments made on a large scale by a company in Mexico which expects to re-treat sand residue. The sand, already clean of slime, was re-ground to practically 200 mesh and has been found to leach nicely even at this fineness. Moreover, the pulp, containing little slime even after the re-grinding, stays in suspension in the filter-box without any special means of agitation and forms a 2-in. cake on a Butters filter-leaf in 20 minutes. At this rate the capacity of the filter is three times what it is under ordinary conditions and it may figure out cheaper to filter this 'all-sand' pulp; or it may be cheaper to give the final water-wash (after air-agitation with wash solutions) in sand-vats.

Another plant has an exceedingly fine slime, which requires a low vacuum at the beginning of filtration to prevent drawing dirty solutions through the filters, and what is worse, drawing slime into the interior of the filter-leaves. This trouble was experienced at first, but the simple expedient of starting gently removed the source of trouble. This filter was too small for the work, being supplied with pulp containing a large proportion of sand. After this coarse sand was removed and it was not necessary to hurry filtration, the solution passed clear enough to be sent to the precipitation-boxes without previous clarification.

Another plant of stamps, with sand and slime vats, expected to place two tube-mills for re-grinding and therefore obtained a filter large enough to wash the (supposed) increased tonnage of slime. This increase did not come with fine grinding, although the filter is now supplied with its full capacity of slime by an increase in the number of stamps. The slime, as it comes from the mill, will settle only to about 1.1 sp.gr. (7 to 1), showing its ex-

tremely fine state, yet the effluent solution from the filter is entirely clear—much better than the decanted solutions, and even these latter are sent directly to the zinc-dust precipitation-vats. The classification is made with cones and considerable slime goes to the leaching-vats and the slime contains little or no sand. For this reason the slime forms a cake uniform in thickness from the top of the filter-leaf to the bottom, and, in spite of the fact that sand is absent, the slime washes evenly and quickly. This is a slime that will not decant much below 78% moisture in 15 hr., which in the design of the plant meant either an excessively large slime-plant of vats for settling or a large loss of dissolved precious metal.

It seems to be proved that no one can tell by looking at an ore or slime, or by testing it merely by concentration and cyaniding, how it will agitate and filter, and that tests to determine its probable mechanical behavior may entirely change proposed practice. Air-lift agitation has solved the problem of cheap and effective agitation of either sand or slime, but from the fact that fine grinding will increase extraction it does not follow that the entire mill product should be treated as slime. When it can be so treated such a plant is, of course, ideally small, self-contained, inexpensive, and easily operated.

Mining in Quebec.

The annual report of J. Obalski, Superintendent of Mines of Quebec Province, for 1906, has just been issued, showing a total output of the value of \$5,019,932 as compared with \$3,755,000 in 1905. Though the figures indicate increased mining activity, neither gold nor silver were produced during the year in appreciable quantities, and the yield of copper ore was only 32,527 tons, valued at \$176,681. Bog iron ore was produced to the amount of 18,331 tons, valued at \$61,175, which was treated at the blast-furnaces at Radnor and Drummondville, the output being 7,851 tons of pig iron, worth \$177,643. The production of chrome iron ore and concentrate was 8,961 tons, worth \$91,834. The largest item was asbestos, the output of which was 61,675 tons, valued at \$2,143,653, as against 48,960 tons, valued at \$1,475,450, in 1905. Asbestos to the amount of 21,119 tons, worth \$18,875, was also produced. The year was also a prosperous one for the mica industry, the yield being 530,086 lb., valued at \$168,887. The output of portland cement from the two companies engaged in its manufacture was 405,103 tons, of the value of \$625,570. The report includes an account of an exploration trip undertaken by Mr. Obalski through the region east of Lake Temiskaming and the Ontario boundary and to the north of Pontiac county, where the same Huronian formation occurs that is found in the Cobalt area. A summary of the results of geological investigation as far as it has been prosecuted in that region is given, showing that it presents a great variety as regards soils and timber and that a considerable breadth of it is traversed by the Huronian belt from Chibogomo to Cobalt. But the Laurentian formation has been found to extend farther north than was hitherto supposed and only islets of the Huronian have been discovered in the surveyed townships east of Lake Temiskaming. While much prospecting has been done, only one company has put up a plant and done development work on indications of chalcopryite in Fabre township. In other parts of the surveyed area galena, chalcopryite, pyrite containing some gold, magnetic iron, and cobalt bloom have been found, but no regular mining work has been done. Gold-bearing quartz has been found at Opasatica and Abitibi lakes; chalcopryite near Fish lake on the Ontario boundary, on the Bell river and on the Harricaw river, north of the transcontinental railway.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ROTARY PUMP.—No. 869,050; Robert M. Blackmer, Conway, Michigan.

In a rotary pump, a pump casing formed with parallel side walls and a cylindrical wall having arcs of different degrees of curvature, said casing having an inlet-port located some distance beyond one end of the arc of smallest radius, and a discharge-port on the opposite side of the cylindrical wall therefrom the orifice of which overlaps the other end of the arc of smallest radius, in combination with a rotary bucket-carrier mounted in said casing concentric with the arc of smallest radius, and a series of buckets mounted in pockets formed in the periphery of said bucket-carrier and having radially swinging blades adapted to engage the inner surface of the cylindrical wall of the casing under centrifugal action, substantially as described.

ROCK-DRILL-FEED MECHANISM.—No. 869,278; Thomas Turner, Ottumwa, Iowa.

In feed mechanism of the class described, the combination with a motor, of means for feeding the same to its work, said means comprising a cylinder and a piston operating therein, means for conducting and admitting fluid under pressure to the cylinder on one side of the piston, and means, located within the cylinder, for varying the effective pressure area of the piston acted on by such motive fluid.

ORE-ROASTER.—No. 869,360; Allen J. Garver, Clarkston, Washington.

The combination of a cylinder, means for rotating the same, a cylinder head closing one end of said cylinder, and provided with apertures and with bevel edges bounding said apertures, means for heating cylinder, and an ore-pan disposed adjacent to the path of travel of said apertures. The combination of a revoluble cylinder, a cylinder head closing one end thereof, and provided with apertures and with bevel edges bounding said apertures, a dust-chamber partially inclosing said cylinder head and said cylinder,

means for supplying ore into said cylinder, and an oven for heating said cylinder.

VENTILATION OF TUNNELS.—No. 869,297; Samuel C. Davidson, Belfast, Ireland.

A tunnel having means for moving the column of air contained therein in a direction lengthwise of the tunnel, such means comprising air-forcing means discharging into such column at a point between the ends of the tunnel, said means delivering a blast of air of a cross-section so much smaller than that of said column, that the quantity of air delivered by said blast shall be insufficient to place the sides of said column under any considerable radial pressure, said blast being directed in such manner as to move the latter in the required direction.

FILTERING APPARATUS.—No. 869,732; David J. Kelly, Salt Lake City, Utah.

In an apparatus of the character described, the combination of a stationary tank, a pressure filter supported therein, a detachable bottom for said tank, and means for detachably locking the bottom to the tank during filtration, said locking means including projections on the tank, tightening rods carried by the bottom and adapted to engage said projections, a screw engaging said bottom, and a nut carried by the said rods and through which said screw operates.

ORE-CONCENTRATING TABLE.—No. 869,860; Frank E. Shepard, Denver, Colorado.

In combination in an ore-concentrator, a table, a frame member therefor, a transversely disposed base on which the said frame member is mounted to turn on its longitudinal axis, supports for the said base on which it is free to rock on a transverse axis, a vertically adjustable support for the said frame member by which it may be rocked with the base on the said transverse axis, and means for adjusting the said frame member upon the longitudinal axis.

FEED-BOX FOR ORE-CONCENTRATORS.—No. 869,293; William L. Card and Frank S. Card, Denver, Colorado.

A feed-box for sizing pulp preliminary to concentration by a concentrator, said box having a bottom inclined transversely downward toward the discharge side, and being provided with riffles.

Jeffrey Mining Machines.

The Jeffrey mining machines with flame-tight motors and starters shown in the accompanying illustrations were brought out almost simultaneously with the publication of the British Departmental Committee's report upon the use of electricity in mines. This report, which embodies rules for the use of electricity in mines, recommended the adoption of entirely enclosed motors and auxiliary devices, such as starters, terminals, etc., for all mines coming under general rule No. 8 of the Coal Mines Regulation Act of 1887.

Mining-machine motors of necessity have to be compact. It is therefore necessary that every advantage be taken of space, so that the motors will not heat excessively under their regular duty. In this country where our mines are free from gas, the open type of motor has found favor on account of its accessibility, and on account of the fact that the same motor-capacity can be put into smaller space in the open type than in the enclosed type. By careful designing, however, the Jeffrey Mfg. Co. has been able to introduce motors of the enclosed type which are of equal capacity to those of the open type formerly used, and the enclosed motors occupy practically no more space than those of the open type.

The Jeffrey 2I-A motor, which is typical of other mining-machine motors made by this company, is modern in every respect. The armature is drum-wound with machine-formed coils. The pole pieces are of laminated sheet-steel, and the windings of both the armature and field coils are insulated in the most approved manner for mining service. This service, by the way, is probably the most severe of any to which electric motors are subjected. The insulation has to withstand both oil and moisture, as well as heat and infinitely more dirt and less attention than in any other service known. The motors illustrated herewith are provided with self-oiling bearings, which are so arranged that the oil hermetically seals the motor so that any gas that may accumulate about the motor cannot possibly be ignited by sparking at the brushes or any interior trouble with the motor. Over the commutator of this motor is a plate-glass door, protected by a heavy malleable iron lid. Through the plate-glass door, the brushes may be observed without opening the motor to mine gases.

Commercial Paragraphs.

R. LINDENTHAL has resigned as manager for the Arthur Koppel Co. and will go to Berlin, Germany, as a representative for American manufacturers.

JOSHUA HENDY IRON WORKS, of San Francisco, reports the following recent sales of Anaconda timber-framing machines: Red Metal Mining Co., for use at its Tramway mine at Butte, Mont.; United Verde Copper Co., Jerome, Ariz.; Anaconda Copper Co., Butte.

THE EMPIRE HAND PROSPECTING DRILL, manufactured by the New York Engineering Co., the well-known gold-dredge builders, of 2 Rector St., New York, has attracted the attention of gold-dredging experts from Alaska and Siberia to Tierra del Fuego; and recent sales are reported in the dredging districts of the Pacific Coast, Idaho, and South America.

They issue a very interesting booklet concerning this drill and its application to prospecting placer ground; this booklet will be mailed on application.

IN the 25 years since the MAYER SHOE Co. of Milwaukee began operations it has outgrown six factories. And in the last six months, during which the last factory annex in Milwaukee has been building, the volume of business has so greatly increased that even with this new annex the output lags far behind the demand. Including the new Seattle factory, which has just been completed, the total capacity of the Mayer Boot & Shoe Co. exceeds 9,000 pairs a day. This remarkable output, together with the inability of the Mayer Co. to build factories fast enough to keep pace with the demand, is most convincing evidence of the high quality of Mayer footwear.

Catalogues Received.

THE DENVER ENGINEERING WORKS CO. has issued Bulletins No. 1,032, 1,033, 1,034. Bulletin No. 1,032 described

Jeffrey Motor for Mines.

their electric hoists, ranging in capacity from 675 to 20,000 lb. rope-pull. This company has ceased to rate its hoists by the horsepower, but instead gives the rope-pull at the drum as it is that which determines the strength of clutches, gears, and brakes. Besides, the weight of the load to be hoisted is the first thing decided upon in a hoisting problem; the speed is determined later, and then finally, the horsepower. Bulletin No. 1,033 describes their line of gear-wheels. This company owns the second largest gear-cutting machine in the United States and is prepared to cut special gearing of any form or tooth outline. They also carry a large line of gears, already cut. Bulletin No. 1,034 describes their rigid rolls for ore crushing. These rolls are cheaper than spring rolls and give little, if any, oversize. These rolls are quite strong and are not broken by ordinary pieces of iron going through them. Among some of the objects illustrated in this catalogue, which have passed through a set of 14 by 27-in. rigid rolls without hurting them is a $\frac{3}{4}$ by 1 $\frac{1}{2}$ -in. steel cap-screw.

Books Received.

'Tables of Quantities for Preliminary Estimates,' by E. F. Hough and P. D. Rice. Published by John Wiley & Sons. 16 mo, iii + 92 pp. Price \$1.25. This book contains tables in regard to cubic yard content of roadbeds, toe-slopes, and end-areas, the acreage of right of ways 100 ft. wide, and conversion tables for feet into miles, feet into chains, chains into feet, and fractions of an inch to equivalent decimals. Editorial.

THE ARTICLE on a part of the State of Chihuahua, in Mexico, relates to an important mining region; and while Mr. A. W. Warwick's description of the topography will be found interesting, it is not too much to say that mining men will be especially grateful for the map prepared by him from his own surveys. The result is a valuable chart of a corner of the world concerning which accurate topographic information has been hitherto lacking.

WE PUBLISH a letter on the methods of cyanidation practised in Nevada, and we hope that it may elicit a useful discussion. At the present time the difficulty in marketing ore is directing attention to the need of local reduction works whereby the output of the mines may be converted into bullion with as little delay as possible. Bullion need not go to banks, it can be sent direct to the Mint, which, in turn, will give the coin now so much in demand.

HOARDING is a phase of unwillingness to lend, it is the concomitant of a financial crisis. It is estimated conservatively that \$75,000,000 has been withdrawn from circulation by American bank depositors. Much larger estimates have been published, but they are wild guesses, without warrant of fact. In three weeks the New York banks suffered a gross loss of \$99,000,000 in cash, but of this about \$35,000,000 was shipped by them to interior points. At Boston and Philadelphia the cash holdings of banks have decreased hardly at all.

GENERAL HESITATION to embark in new enterprises is apparent on every side, but there is an immense volume of business that continues uninterrupted and, like a great fly-wheel, it will shortly steady the erratic movements of other parts of the industrial machinery. Thus, during the six months ending on November 1, the Allis-Chalmers Company, on orders, shipped an enormous quantity of machinery, ranging from 11,886 tons in May to 13,910 tons in October. We are informed that, while there has been some decrease in contracts for future delivery, the receipt and installation of machinery by the large industrial companies continues.

MEXICO is suffering from the financial depression, as is every region dependent upon the health of the money centres. Up to the end of October, everything in the southern Republic seemed on a solid basis, business was good, money was being made cheerfully, and the future was bright with promise. The first sign of trouble coincided with the stop of inflowing money, as was presaged by the check to the big railroad consolidation. Then two or three large enterprises, such as the Guadalajara Electric Power Development Co., and other

undertakings awaiting the aid of foreign money, were halted. This made the banks cautious. Then came the crash in New York and now the local banks will not lend money, restricting themselves to the renewal of old paper, by which method they are extending valuable assistance, but restricting industrial development. There is no sign of a scare and there is every confidence that Mexico's progress is delayed only temporarily.

D ICTIONARIES are not exhilarating literature, nevertheless it is proper that they should be studied by people who undertake to write glossaries of technical words. In the *Yreka Journal* we find a list of mining terms, containing many needless errors, all of which could have been avoided by reference to a dictionary, such as the Standard, for example; we mention this particular dictionary because we happen to know that William Henry Pettee, formerly professor of mining engineering in the University of Michigan, edited the mining and metallurgical terms; and Pettee was a scholar of the most conscientious type. He died in 1904. Our northern contemporary defines 'infiltration' as "the theory that the vein filling is introduced by an igneous fluid and solidified." 'Heading' is given as "the vein above the drift." 'Carbonates' are "salts containing carbonates" and 'cropping out' is defined as "the raising of layers of rock exposed at surface." Other blunders might be quoted; in fact, the glossary is mostly blunders. They are well meant, but more likely to confuse than to instruct. Any dictionary would do better.

The Ore Market.

S MELTER RATES on silicious ores in the West have been raised, both by the smelting companies themselves and the ore purchasing companies. The reason given out is the congestion of traffic on the railroads, causing excessive delay in the transfer of bullion from the Western smelters to the Eastern refineries. For example, at one time as many as 96 cars of bullion were stalled between Salt Lake and Chicago, this amount representing the month's output of a large smelter, such as the Murray plant. The Selby smelter is loaded with silicious ore from Nevada, having received in October four times the amount usually assimilated in its lead-smelting operations. The Salt Lake smelters are similarly situated and, in consequence, some of the Nevada ore is being diverted to Denver. The local rates quoted at Goldfield have gone up by reason of a cumulative increase levied by smelters and samplers; this amounts to over 50 per cent on the lower-grade ores, the increase being credited to the additional cost of freight caused by shipment to more distant points. In the meanwhile every stamp-mill and cyanide annex in Nevada is being examined and overhauled with a view to bringing it into service, for the cost of freight and smelting is so high as to stimulate the ingenuity of the wet metallurgists. We expect to see the smelters relieved of an excessive supply of silicious stuff and we anticipate a further useful development in cyanide practice.

Financial Correctives.

A MONG the absurd suggestions precipitated by the financial crisis, none will amuse mining men so much as that of the hair-brained enthusiast at Goldfield who suggested the stamping of bits of bullion in order to add to the currency. Reference was made to the 'slugs' that passed current in the days of the Argonauts and mention might have been made of the gold dust used even recently as money in the Alaskan mining regions, as it had been employed in the early days of Western exploration and development. Of course, the scheme is impracticable. The minting of money is one of the first perquisites of government, and the difference between coinage and intrinsic values is one of the primary taxes paid by civilized communities. To stamp bullion with its value is to make coin. That is illegal. To circulate bits of bullion without stamping would require weighing at each transaction and even that would be an incomplete precaution, for counterfeit gold is not difficult to manufacture. It will be better to discard such childish expedients for the expansion of a shriveled system of currency and to set to work milling the ore of the rich mines at Goldfield and elsewhere in Nevada. If they produce bullion they need not delay in getting it converted into something better than cubes or pellets of their own manufacture, for the Mint at San Francisco will receive the base bullion and provide its equivalent in United States coin.

Favorable comment has been made on the action of the Federal authorities in putting a large amount of Government securities at the disposal of the banks in order to relieve the stringency in currency. But it may well be asked, if the cause of the depression in 1907 was the boom of 1906, and if the effects of the depression are to be minimized by Federal action, why was not the cause controlled in a similar way? An ounce of prevention is worth a pound of cure. Would not the present panic have been avoided by restraining the boom that gave rise to it, and if we applaud the Government and the President for applying restorativeness today when the patient is sick, would we be equally willing to commend the Federal authorities for a course of action that, if set in motion a year ago, might have prevented the ills which have befallen the body industrial.

The earnest attempts of President Roosevelt to cause people to discern the difference between good corporations and bad corporations, between business and depredation, have been most heartily condemned by the financial people of the East. What would they have said in 1906 if the President had caused the Department of Commerce and Labor to issue a bulletin denouncing the sale of a hundred leading stocks at too high prices, and denouncing twenty-five or thirty prominent flotations as practical swindles? We can well imagine the storm of indignation and protest that would have been aroused by such a proceeding and yet it would have been far more to the point than the course the Government has taken now. It is evident that the public will not

endure the interference of the Government with a view to making financial operations more rational and legitimate during times of expansion and buoyancy; if this be so, then it appears illogical to ask the Government to interfere when things go wrong by reason of financial recklessness.

Periodicity of Panics.

WHEN trouble comes, it is some sort of consolation to know that it must come, and it may be a further solace to be informed that it comes at regular intervals. Economists tell us today that a panic is due every ten years and the talk of decades gives a spurious sort of scientific precision to their vaticinations. But we find that panics occurred in 1857, 1873, 1884, 1893, 1901, and 1907, so that the orbit of a panic is as erratic as that of a comet, being perturbed by factors far beyond our ken.

Panics are accidents that come regularly at the close of a cyclical period of business activity, just as a smash will supervene to a motorist who persists in going too fast along roads of uncertain character. We have seen a typical cycle between 1894 and 1907. First a recovery from the previous collapse, then a slow return of prosperity in the wake of renewed confidence, culminating gradually in a remarkable agricultural and manufacturing output, a rapid increase of gold production, an expansion of export trade, and an extraordinarily favorable position in international exchange. Then ensued an accumulation of capital, which, in turn, stimulated speculation and led to the re-capitalization—on a crescendo scale—of every form of American enterprise. All went merry as a marriage feast, but the pace was too rapid for safety; the first rupture in the chain of business relationships was bound to be a break-down. It came. The over-extension of credit caused a débâcle on the Stock Exchange at New York and that precipitated a financial stringency all over the country. The collapse was primarily due to the destruction of credit in the banking community.

The relation between the New York banks and the New York Stock Exchange is the fruitful source of many troubles. The country banks are compelled by law to hold a specified minimum reserve; in order that the reserve shall not be unproductive, they place it with the New York banks at interest; and the New York banks must use the money where it is subject to call, so they lend on call to speculators. Thus speculation and banking become allied organically. Last year the Western banks held credits of \$500,000,000 in New York banks. When an untoward event drives the Wall Street gamblers to cover, they ask the banks for help, and if that appeal comes when the Western credits are needed to move the crops, there is a first cause for a stringency; and if such a combination of circumstances arrives at the close of a period of speculative debauch, everything is ready for a panic, which comes without any regard for the decennial period of the historian or the belated prophecies of the economist.

The relation between speculation and banking gives Wall Street a sinister prominence and leads to a dangerous concentration of financial interests. Banking collateral is placed in an exposed position. The country banks try to draw down their deposits in New York and this undermines the basis of credit. So well is this relationship recognized now that many proposals have been made to remedy it; among sundry alternatives we may mention the asset currency suggested by the Hepburn committee and the idea of a central bank, recommended by a San Francisco banker. Undoubtedly some measures will be taken to adapt the currency system to the expanding necessities of our continental business. We shall hear of many other schemes, and old fallacies will be revived. Already we have Mr. Bryan's proposal of Government insurance of the deposits in national banks and we have the suggestion of a wild man in Nevada that bits of bullion be stamped and circulated.

This sort of hysteria marks the culmination of a panic. Then will come a calm, with signs of temporary stagnation; we shall have a relaxed condition of production, entailing economic waste, but this sequel to the interruption of industrial progress will be brief as compared to previous similar periods, because America is stronger and more self-sustaining than in past times. Agriculture and mining are in a healthy condition, relative to other countries, and the vigor of these basic industries ensures a speedy return to normal conditions. The growling of the bear will be silenced by the bellowing of the bull, and both will once more unite to silence the bleating of the lamb. The human mind oscillates between two extremes, the hope of gain and the fear of loss. As one weakens, the other strengthens. And with a pathetic waste of experience that is so essentially human, people will cease to care whether panics are periodic or not, and they will be as inclined to accept the idea that panics are intimately related to the appearance of sun spots as to impute them to the human tendency to over-reach, to get something for nothing, to see swans where lame ducks go to water—that water which the Wall Street financier turns into golden wine, and then marvels if the miracle be not repeated.

We conclude that panics have no regular periodicity, they are to be foretold only as a part of the recurrent human cycle of exaggeration and depreciation, of ebullition and prostration, of hope and despair. And so we fall back on the analogy borrowed from geology and liken a panic to an earthquake—for we know them both only too well. According to the State Earthquake Commission: "The cause of these movements in general terms is that stresses are generated in the earth's crust which accumulate till they exceed the strength of the rocks composing the crust and they find a relief in a sudden rupture." Which being translated means that the financial pie-crust of promises to pay becomes too thin to be self-sustaining, so that finally it breaks, permitting a sudden escape of the steam-laden air so closely associated with the indigestible securities underneath, much to the mortification of the financial chefs and the general disappointment of the human family.

By the Way.

In the fifteenth annual report of President Schuman of Cornell University, we find some valuable comment on the education of engineers. He says:

The Director hopes that at least the best students may broaden out their education by electing subjects in the liberal arts in addition to the prescribed curriculum in engineering. Occasionally this will happen, and the President is personally acquainted with a senior in engineering who last year elected a course in metaphysics in which too he did excellent work. Such men derive incalculable benefit from arts subjects, not only because they are capable, earnest, and studious, but also because they are already well-grounded in physical science. The pity of it, however, is that the number of them is so small. Nor can more be expected so long as they are required to take, besides these arts subjects, a technical course which occupies the full time of undergraduates.

The courses in engineering require either 17 or 18 hours for each of the four terms of the first two years, or 70 hours in all. In Civil Engineering 38 of the 70 hours are in Arts and Sciences and in Mechanical Engineering 34. In the junior year the Civil Engineers also take a course in political economy of three hours a week throughout the year—a course which the President has urged should be prescribed also for Mechanical Engineers (for whom next year, at any rate, the Faculty have prescribed a one hour course). If this course of six hours for the two terms be added to the foregoing figures, the Civil Engineers will have 44 hours in Arts and Sciences and the Mechanical Engineers 40.

Excellent as the courses in Arts and Sciences which are taken by freshmen and sophomores in engineering are and have been, and valuable as the education they furnish is, both the courses and the education suffer, from the point of view of general or liberal culture, from the disadvantage of being exclusively in the field of mathematics and physical science.

The modern engineer, if he is to be truly educated, needs a training broader than physical science and technical study. He, too, because he is a man, needs the culture of the humanities—that liberalizing and expansion of mind which comes from the study of literature, history, and philosophy. This, however, he can no longer secure in a four years' technical course. With the constant increase of professional subjects rendered necessary by the advance of engineering science and the practice of modern engineering, the curriculum of the four year course has grown more and more technical, and less place than ever now remains for any of the liberal arts. The result is that, all over the country, men are graduating in the engineering courses with an ignorance of literature, history, and the other liberal arts so dense that no proficiency in science and technology can save them from the charge of being uncultured, especially, when, as so often happens as a necessary result of their limited reading of literature, they are unable to express themselves, either in speech or writing, in correct English prose. Has not the time arrived when the period of study for students in engineering should be extended beyond four years so that students may be required to study the elements of a liberal education before entering upon their strictly technical work? The President believes that along this line the next step is to be taken for improving the education of engineers at Cornell.

Two methods are open, though perhaps only one is feasible at the present time. Either one year or two years of study might be prescribed in addition to the present curriculum of four years, and the time thus gained devoted by the student mainly, if not indeed ex-

clusively, to the humanities. Of technical study he already gets enough in the last two years of the course and of pure science he has enough in the first two years. It has already been shown that of the 70 hours prescribed in the engineering courses for the first two years from 40 to 44 hours are taken in the College of Arts and Sciences, of which all but six in economics are in physical science. What the engineering student needs, therefore, to broaden his horizon and to humanize his culture is the study of literature, history, and other humanities. And he would derive unusual advantage from those studies since, while taking them, he would also be studying the mathematics, physics, and chemistry prescribed in his curriculum. If six years of study were required of him, the student in engineering could complete in the first three years the 40 to 44 hours of science now prescribed and in addition about 50 hours in such humanistic studies as literature, history, political science, etc., while in the last three years he would devote his mind, enlarged and vitalized by the study of the liberal arts and of physical science, to the mastery of the technical subjects in which he could not fail to show a facility and superiority of work which it would be unreasonable to expect and difficult to discover among the students so much less liberally trained, who now pursue the four year courses in engineering. Such a six year course would admit the student to both the A. B. and the C. E. or M. E. degree without any change in the existing rules.

It has hitherto been possible for students to take the arts degree and the engineering degree in six years. A few have availed themselves of the privilege, but the number has always been small. For this and other reasons the President believes it would be going too far at the present time to require all candidates for a degree in engineering to spend six years in study and secure the A. B. degree as well as the professional degree. But the President also holds that it is very desirable that young men should have some college training in language, literature, history, etc., before entering upon their professional studies. And he is disposed to think that the time has arrived when Cornell University might safely insist on a fifth year of study in the engineering courses, the additional time to be spent wholly on humanistic studies during the first two years of the five year course while the student was also pursuing his work in pure science—mathematics, physics, chemistry, etc. This plan would, of course, not be so near the ideal as a six year course, but it would be a great improvement on the present arrangement, and that not only because it afforded to prospective engineers the means of securing at least some culture from the humanities but also because it would infallibly awaken interests and stimulate tastes which would induce them to pursue these studies further in the years that followed. Indeed many of them, noting that two degrees could be obtained by an additional year, might go on to the six year course in arts and engineering, even though at entrance they had not contemplated more than the five year course which the President believes should be prescribed in the near future. With this presentation of the case he recommends the matter to the earnest consideration of the Faculties and Trustees. He himself is persuaded that no improvement which could now be effected in the character of the instruction offered by the technical colleges at Cornell University could compare with the gain which would accrue to those colleges by having the minds of their students nurtured, strengthened, and liberalized as they might be if the students devoted even half their time during the first two years of the course to the English language and literature, history, political science, and other subjects of humanistic culture.

Personal.

H. JULIAN is at New York.

CHARLES BUTTERS is at Washington.

ALGERNON DEL MAR is at South Pasadena.

L. D. RICKETTS was at Hermosillo recently.

ANDRE P. GRIFFITHS is on his way to Brazil.

W. A. CALDECOTT returned to London on the *Baltic*.

W. H. ARGALL has returned from Uruguay to London.

F. T. BYRDE has returned to London from Liberia, in Africa.

EDWARD JUSSEN has returned to Spokane from Ely, Nevada.

JOHN OVERBERRY has returned to San Francisco from Goldfield.

FRED. B. REECE has returned to Denver from a holiday in Europe.

CHARLES D. KAEDING, recently in Korea, is now at Goldfield, Nevada.

FRANK W. OLDFIELD has returned to Los Angeles from Prescott, Arizona.

C. L. HARGRAVE is assayer at the Combination mine, Goldfield, Nevada.

H. C. CARR is superintendent of the Herman mine at Westville, California.

LEE S. WOODS is manager of the Green Mountain mine, near Silverton, Colorado.

SARAT C. RUDRA is operating in Sierra county, but his office is in San Francisco.

JOHN E. HARDMAN, of Montreal, has been examining mines in New Brunswick.

L. N. B. BELLOCK is returning to Copala, Mexico, after a visit to his home at Halifax.

O. N. FRIENDLY is an assistant engineer for the Daly West mine, at Park City, Utah.

H. L. SWAIN is manager for the Pacific Copper Co. at Zihuatanejo, in Guerrero, Mexico.

C. W. PURINGTON is on his way from Vladivostok to London, by way of St. Petersburg.

JOS. T. WOLFE, chief engineer for the Tonopah Mining Co., in Nevada, is in San Francisco.

CHESTER NARAMORE, in the Denver office of the U. S. Geological Survey, is now at Washington.

F. B. CLOSE, until recently general manager for the Helvetia Copper Co., Arizona, is in Sonora, Mexico.

W. R. BASSICK, whose office is at 605 Atlas Bdg., San Francisco, is the local agent of the Bucyrus Company, of South Milwaukee.

ROBERT B. BRINSMADE has been selected as president of the State Mining School, at Platteville, Wisconsin. He is a graduate of Washington University and Lehigh.

G. L. EDDY, recently assayer for the Mountain Copper Co., at Keswick, Shasta county, has accepted a similar position with the Confidence mine in Tuolumne county, California.

Obituary.

DANIEL T. MONTGOMERY, a native of Rock Island, Ill., died at Vantanas, State of Durango, Mexico, on October 30, at the early age of 25 years. He was the son of Mrs. Jane T. Montgomery. His mother, five sisters, and three brothers survive him. For two years past he was engaged by David John Pullinger of London, England, as field assistant to F. C. Roberts. He had attended the Colorado School of Mines and later graduated from the mining engineering department of the University of California. He was a skillful engineer, possessed of high ideas of honor and integrity, a gentle and charming companion beloved by all who met him, a truly Christian man, whose premature death is not only a severe loss to the engineering profession, but is deeply regretted by all with whom he came in contact.

General Mining News.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The flow of gas, encountered on the 16th in the various shafts of the Copper Queen Consolidated Mining Co. and the Calumet and Arizona Mining Co., has been completely overcome by compressed air lines introduced into the lower levels of the shafts. For two days the men were unable to stay in the drifts owing to the great amount of gas on the 950 and 1,050-ft. levels of the Irish Mag and the 600 and 700-ft. levels of the Spray and Gardiner shafts. A number were overcome by the fumes, but soon gained consciousness when brought to the surface. A difference of opinion exists in regard to the character of the gas, but it is generally supposed that it originated in the unworked stopes, caused by water from the surface coming in contact with the decomposing sulphides. For a long time a block of ground comprising about twenty acres and down to a depth of 500 ft., between the Czar and Spray shafts of the Copper Queen Company, has been slowly sinking, varying in places from six inches to three feet. This left huge cracks on the surface into which the waters of the recent rains poured, coming in contact with the sulphides, and probably caused the gas.—Diamond-drill work, which has been vigorously pursued for the past month on the flats of the Warren Realty & Development Company's property has reached the 500-ft. level and still shows only the gravel wash from the mountains.—A blaze was discovered coming from the shaft of the Shattuck-Arizona Mining Co. at about one o'clock on the morning of the 20th. Efforts were made to quench the flames with water, but to no avail. An entrance was attempted from the Cuprite shaft of the Copper Queen Company, but owing to the dense smoke had to be abandoned. After fighting the flames for about twelve hours a plan was suggested to smother the fire by closing all entrances to the mine. This was successful. The estimated loss to the timbers and machinery of the mine is about \$20,000. The fire bears no relation to the gases, which the Calumet and Arizona and the Copper Queen companies have been fighting the past week, as the Shattuck lays more than a mile distant from these properties. The origin of the fire is unknown, as there were no men in the mine after four o'clock of the previous day, there being only a day-shift working during the curtailment in production. It is generally supposed that it started from spontaneous combustion from the gases in one of the stopes.—The machinery of the machine shops of the Calumet & Arizona Mining Co. has been moved from the old shops at the Irish Mag shaft to the new shops at the Junction shaft.—The steel frame-work for the large new power-house of the Copper Queen Consolidated Mining Company has been completed. Bisbee, Nov. 21.

A body of copper-bearing sulphide ore has been found on the 900-ft. level of the Emerald mine, belonging to the Tombstone Consolidated M. Co. This orebody is about 200 ft. below water-level; the ore carries some silver. The amount of water being pumped daily at the Tombstone Consolidated is 500,000 gal. less than it was Oct. 1; the water-level is being gradually lowered.—It has been impossible to ascertain as yet (Nov. 24) the extent of the damage at the Shattuck mine at Bisbee, as the bulkheads are still in place. The working forces at the Bisbee mines are about the same as last week. At the Wolverine & Arizona the drift, developing the orebody discovered about two months ago, has passed through 125 ft. of ore.—Some stringers of rich ore have been found on the 65-ft. level of the North Bisbee property in Tombstone canyon.

YAVAPAI COUNTY.

Judge Lanning, of the United States Court, at Trenton, N. J., has appointed J. Kearney Rice, of New Brunswick, N. J., receiver for the Arizona Smelting Co. and the Consolidated Arizona Smelting Company.

CALIFORNIA.

AMADOR COUNTY.

At the Valparaiso a large station has been cut at the end of the adit, which is 200 ft. long. This station is large enough for a horse-whim to be operated in it. A winze has been sunk at this point; this is at present 25 ft. deep and will be continued to a depth of 100 ft. before commencing to drive on the vein. Several rich pockets of ore have been found along the adit, but these appear to be worked out; as the Mammoth mine, which joins the Valparaiso on the south, had many pockets of ore below the present level being worked at the Valparaiso, it has been determined to also develop this property in depth.

CALAVERAS COUNTY.

At the Chapman mine, on the main San Andreas channel, the adit is being rapidly advanced.—At the Central Hill mine, the mill is working full time on gravel coming from this drift mine.—At the Cassinelli mine, near the North Star mine, the old channel has been cut. The gravel is quite rich and the channel is large.—At the North Star mine new machinery is being added to the plant.

NEVADA COUNTY.

(Special Correspondence).—A new compressor has been installed at the Empire, and the pumping capacity increased. These additions are expected to enable the property to be operated continuously throughout the winter. The 40-stamp mill is running constantly on good ore. George W. Starr is superintendent.—The Central shaft is now 5,000 ft. deep, and is still being sunk. Development work is being done at several points; the vein is looking well.—Considerable work is being carried on at the Sultana group, and a large force of men is employed. Operations are carried on through the Prescott Hill shaft. C. K. Brockington is superintendent.—The new five-stamp mill at the Austin has been completed. The mill was built in 15½ days, which is claimed to be the State record. As soon as the pipe-line is finished crushing will commence.—The Grey Eagle Co. is making preparations to install a hoist, concentrator, and sand plant at their property, near Maybert. C. C. Weisenburger, R. L. Hathaway, and John Anderson of Nevada City have obtained a contract to improve the mill. The property is looking well, and the 10-stamp mill is running on good ore.—Excellent ore is being developed at the Mountaineer mine. The company controls a large area of rich territory; the main vein is showing up well.—Owing to the financial stringency several small properties of this district have been compelled to temporarily suspend activities, while the pay of the men is delayed at many others. The larger mines have been shipping their bullion to the Mint at San Francisco, and by this means have succeeded in obtaining sufficient gold coin to meet their requirements.—Men are pouring into Grass Valley and Nevada City from many other camps, and work is becoming scarce. The largest influx is from Arizona and Nevada points.

Grass Valley, Nov. 25.

The Aurora mine at Randolph Flat has closed down temporarily. The shaft is now 41 ft. deep and follows a vein 2 ft. wide, which is of good grade. As soon as the financial flurry is over, work will be resumed.—A. A. Charonnat, superintendent of the Canada Hill and the Grey Eagle mines, near Maybert, has located a new claim above the Grey Eagle. While climbing a hill he tripped on a rock which, upon examination, proved to be quartz carrying some free gold. This will be developed immediately.—Michael Hogan has struck good ore in a shallow shaft on his claim, the Hendrick, east of Grass Valley. The vein-filling is 7 ft. wide, 3 ft. of which is of milling grade. This property adjoins the old Eureka mine.

For the first time in 40 years many white men are working with rockers along the banks of the South and Middle Yuba rivers above Nevada City. For years past Indians and Chinamen have mined along the river. Invariably, when asked what they were making, they said four to six bits per day. This was believed, but the results of the work this fall has led white men to think that the Chinamen have made good

MICHIGAN.

KEWEENAW COUNTY.

The No. 2 shaft on the Kearsarge lode being sunk by the Allouez M. Co. is now 900 ft. deep. The work is being somewhat delayed by the fact that the trap rock, through which the shaft is now passing, is much shattered and large slabs break away from the sides, requiring the handling of more rock and necessitating more timber to fill these places. At 200 ft. this shaft passed through the Osceola amygdaloid, but at that point the amygdaloid is unpromising. The No. 2 shaft is about 1,000 ft. west of the line of strike of the strata at No. 1 shaft. The shaft was so placed, owing to the heavy flow of water met at the locality first chosen. The sixth level of No. 1 shaft is now considerably east of the projection on it of No. 2 shaft. A cross-cut is to be driven to meet No. 2 shaft, which will be at a point 1,750 ft. below surface. This drift will be driven with a grade toward No. 2 shaft. A large hoist, having a drum 14 ft. diam., is to be installed at No. 2 shaft. This hoist was formerly used at one of the C. & H. shafts.

NEVADA.

ESMERALDA COUNTY.

The output of the Goldfield district for last week was 5,801 tons of an estimated value of \$674,200. The different properties shipped the following tonnages: Mohawk Combination, 3,490; Mohawk, 1,046; Rogers Goldfield Syndicate, 132; Florence L. & M. Co., 57; Diamondfield Black Butte, 18; Florence Annex, 36. The Combination mill treated 595 tons; the Kinkead mill treated 125 tons.—Neither the Mohawk-Jumbo nor the Little Florence are shipping.—The Florence Annex Co. shipped from its lease on the Cornishman and Firelight claims the richest car of unsorted ore ever shipped from Goldfield. The car contained 40 tons of ore assaying \$948 per ton, a total valuation of \$37,920. The ore came from the 300-ft. level. The record shipment made last winter by Hayes & Monnette was of sorted high-grade ore, that had been saved for several months. As the Florence Annex Co. has obtained enough money from its shipments to work its lease for a considerable length of time, it has decided to store its ore at the mine until the smelters are able to make settlements within a reasonable time. Development continues on the 400 and 500-ft. levels; last week the vein was cut on the 400-ft. level and a drift on the vein has been started; as yet no high-grade has been found on the 400.—The frame structure for the Florence mill is almost completed. As yet the machinery for the mill, although ordered long ago, has not arrived.

The Consolidated is still hunting for a mill. The company has decided to stop shipping until smelting charges are reduced. All miners at the Mohawk, who were working in ore, have been put on development work. The Red Top and the Combination mines are stoping, as the ore is treated in the Combination and Kinkead mills and not shipped. The company will not begin to build its proposed mill until another level, the 600 ft., has been developed. A winze is being sunk from the 450-ft. level of the Mohawk and also one from the 520-ft. level; both are entirely in ore.—What is thought to be the continuation of the Red Top vein has been found in the Macmillan-Halloran lease on the Miss Jessie claim of the Laguna group. The vein was cut in the shaft at a depth of 365 ft. but was quite low-grade; at the present depth, 404 ft., the ore has improved until it is almost of shipping grade. On the 400-ft. level driving will begin soon; the shaft will be sunk another 100 ft.—The Little Florence Co. has cut the orebody on the 625-ft. level; a cross-cut, 20 ft. long, has been driven without sign as yet of the hanging wall. The ore is of shipping grade.—At the Sandstorm mine the Parkison & Erbel are sorting out 50 to 80 sacks per day from the ore hoisted at their lease.—Last week a vein of rich ore was cut at a depth of 110 ft. in a shaft on the west side of Red Mtn., which is about 3 miles east of Diamondfield and about 7 miles northeast of Goldfield. This is on the property of the Diamondfield Red Mountain M. Co. On the nearby Butte Boys claim good ore has been found at a depth of 260 feet.

NYE COUNTY.

The shipments from Tonopah last week were as follows: Tonopah Mining Co., 909 tons; Tonopah Extension, 95; Belmont, 105; Jim Butler, 96; Midway, 104; total, 1,309 tons. The Tonopah company sent 2,650, the Belmont Co. 1,050, and the Montana-Tonopah Co. 1,260 tons of ore to the mills this week. This makes a total shipment for the week of 6,169 tons; assuming that the shipping ore assays \$70 per ton and the milling ore \$30 per ton, the production was \$240,130.—Richard G. Park of Philadelphia has been elected president of the Tonopah-Belmont Development Co. to succeed John W. Brock. About a month ago a 3-ft. vein was discovered on the 800-ft. level in the Occidental claim at a point about 800 ft. southeast of the Desert Queen shaft; but the recent rumor in regard to a new discovery near that point has not been confirmed. This ore is of good milling grade. The diamond-drill hole, being drilled from the 900-ft. level, is 200 ft. deep; progress has been delayed by the shattered condition of the ground. Forty stamps at the 60-stamp mill belonging to the Belmont company at Millers were crushing last week.—At the West End Consolidated the station of the 320-ft. level in the new two-compartment shaft has been completed. Last week the drift from the 275-ft. level of the old shaft, broke into the 320-ft. station of the new shaft. Sinking has been resumed in the new shaft. This has been equipped with a cage; for the present only waste will be hoisted through the new shaft, while all ore is hoisted through the old one. Stoping is being pushed on the 400-ft. level.—At the Midway the new vein, recently found on the 800-ft. level, is being developed; the ore is high-grade and the vein quite large. Most of the ore at present stoped comes from the 435-ft. level. The north cross-cut on the 1,050-ft. level of the Tonopah Extension is progressing rapidly; several stringers of good ore have been cut recently. Stoping is being done on all the levels above the 600.

In the Bullfrog district affairs are in much the same condition as last week. The Colorado Iron Works of Denver has secured the contract for the Homestake mill. This will be a 25-stamp mill and will cost, including the pipe-line to supply water, about \$200,000. The contract calls for the completion of the plant by April 1, 1908. The ore will be crushed by gyratory crushers, stamps, and tube-mills and will be amalgamated and cyanided. Two Hendryx agitators and a Butters filter will be used.—Some very rich ore has been found in the cross-cut recently started at the National Bank. The streak of shipping ore is 2 ft. wide.—The Shoshone mill is treating 150 tons of ore per day. As soon as the new screens for the mill arrive, another shift will be put to work at the mill.—The Gold Bullfrog M. Co. has struck a good flow of water at Sardora spring, about 1,900 ft. from the company's mill. This will furnish plenty of water in the future for the mill.

BRITISH COLUMBIA.

The Consolidated M. & S. Co. of Canada, Ltd., has declared a quarterly dividend of $2\frac{1}{2}\%$; this dividend amounts to \$133,880, making the total dividend paid to date by this company \$848,825. The Consolidated company operates the Centre Star-War Eagle mines at Rossland, the St. Eugene mine at Moyie, the Eureka group near Sandon, the Snowshoe-War Eagle groups near Phoenix, and the Trail smelter and refinery.

BOUNDARY DISTRICT.

The output of the mines for October was as follows: Granby mines, 86,711 tons; B. C. Copper Co. (Mother Lode, 17,909; Emma, 5,697), 23,606; Dominion Copper Co. (Rawhide, 8,287; Sunset, 2,979; Mountain Rose, 95), 11,359; Snowshoe, 25,025; Riverside, 30; total, 146,731. Assuming that the Boundary ores averaged 23 lb. copper per ton, the production of the Boundary mines was 3,604,713 lb. This week the Boundary mines have laid off most of the miners, about 2,000 men being discharged. Preparations are being made to blow out the furnaces at the smelters. The Granby company has laid off 900 men, 550 of whom worked at the mines. At the Snowshoe mine 150 miners were laid off.

EAST KOOTENAY DISTRICT.

At the Sullivan smelter, situated at Marysville, three new furnaces are to be installed; this will double the present capacity. The smelter now treats 120 tons per day. A reserve of 8,000 to 10,000 tons of ore is kept at the smelter in case of trouble at the mine, but at present the mine easily sends 120 tons daily to the smelter. Recently a good body of ore has been discovered north of the old workings on the 100-ft. level. A shaft is being sunk; at present this is 140 ft. deep. As soon as this reaches the 300-ft. level a cross-cut will be run to the present workings. About 50 men are working at the mine.

The ore shipments during the last week from the East Kootenay district were as follows: Sullivan, 600 tons, making a total for the year to date 27,000 tons; St. Eugene, 663, making a total of 21,450; North Star, 71, making a total of 2,751. The Sullivan and the St. Eugene are the largest lead mines in British Columbia at present producing.

ROSSLAND DISTRICT.

The shipments from the Rossland mines last week amounted to 6,365 tons. The Centre Star shipped 3,635 tons; Le Roi, 2,135; Le Roi No. 2, 595. The shaft at the

Map of Part of British Columbia.

Idaho mine is 245 ft. deep and is still in ore. The orebody on the fourth level of the Idaho is looking well as development proceeds.—The 600-hp. Westinghouse synchronous motor, which has been installed to run the air-compressor at the War Eagle is working finely, as is also the 650-hp. induction motor installed at the Centre Star. The Nickel Plate compressor has been shut down. The Le Roi company has stopped prospecting with the diamond-drill at the Spitzee mine, but it will be resumed later. The section of the mine west of the Josie dike has been developed in four levels for a distance of 300 to 400 ft. west of the dike and a considerable tonnage of good ore has been developed.

SLOCAN DISTRICT.

The Kootenay Ore Co.'s plant at Kaslo has enough ore on hand to keep it running for four months.—The Canadian Zinc Co. intends to complete its experimental plant near Nelson. This plant will use electric smelting for reducing ores.—At the Rambler-Cariboo mine, 45 men are working; five earloads of high-grade ore, which came from development work on the 8th and 9th levels, were shipped last week.—At the Bluebird property, on Woodbury creek, belonging to Erie Johnson, five men are working. A cross-cut is being driven to develop the vein in depth.—The Ruth mine and mill are working, but the concentrate is being held at the mill awaiting shipment to the Kootenay Ore Co.'s zinc mill. The Ruth mill will run as long as the

supply of water lasts. About the same-sized force of miners will be kept at work all winter.

MEXICO.

CHIHUAHUA.

The Granadena mill is crushing from 70 to 80 tons of ore per day from the Mercedes mine and making about 12 tons of first-class concentrate.—The American S. & R. Co. is rushing the bullion from its smelter to the United States mint, but the silver and copper is being held.—Owing to the shut-down at Cananea and other camps in northern Mexico, there is plenty of Mexican labor available now. Many companies are preparing to do much development work while this labor is available.—Anderson & Seabell are shipping to the Torreon smelter three cars of ore weekly from their Santa Elena mine at Terrazas, 25 miles north of Chihuahua. The shaft is at present only 50 ft. deep.—The Lluvia de Oro Gold M. Co. has purchased a complete power-plant for its mines and reduction works. The main unit is a 500-kw. alternator, directly driven by an Allis-Chalmers steam turbine.

(Special Correspondence).—The mines and smelter of the Rio Tinto M. & S. Co., are at Terrazas, 25 miles north of the city of Chihuahua. The orebodies on this property have been developed by vertical shafts, gasoline hoists being used. The deepest work is the 300-ft. level, but most of the ore mined has come from the 200-ft. level. The ore occurs as lenses in limestone, close to the contact of this limestone with porphyry, and consists of copper carbonates in a gangue of calcite and garnet. It is said to carry from 2½ to 3½ copper, together with gold and silver amounting to \$4 per ton. The mine is an old one; the more recent operations began two years ago. The present smelting plant was erected at that time under the direction of David Goodale, manager of the company. One copper furnace has been in operation for some time, but the plant was closed down a week ago by reason of the slump in copper prices. Smelting will probably be resumed within the next two months, as Mr. Goodale states that his company can make money with copper at 14c. per lb. In the meantime the company is sinking in the hope of reaching the sulphide ores. A second copper furnace is on the ground and it may be installed next year. The headquarters of the Rio Tinto company are in New York City, M. J. Condon being president.—The San Rafael mine, where the formation is similar to that at the Rio Tinto, is being developed by three vertical shafts. J. P. Hutchinson and M. D. Murray are concerned in these operations.—The Columbia, lying west of the San Rafael, is owned by the Dragoon M. Co. of New York. It has been under lease to Felix McDonald, who has mined \$75,000 worth of ore from it within the last two years. Mr. McDonald formerly owned the Wisconsin and Shamrock, which were purchased some time ago by E. M. Ray as the representative of Mr. Barnsdale, of Pittsburg. Mr. Ray is at this time at Chihuahua on business for Mr. Barnsdale in connection with this purchase. The properties in question are producers of silver and lead ores of good grade, much of which is said to be below water-level. It is planned to resume work next spring but pumps will have to be installed first. These properties are about a mile from the Rio Tinto and are also in limestone.

Terrazas, Nov. 22.

DURANGO.

Much ore has been blocked out in the La Perla mines in the Topia district. These mines were purchased by M. E. and Bernard MacDonald, of Guanajuato, about a year ago, and the La Perla Mining Co. was organized to operate them, but none of its stock has been put on the market. The ore is silver-lead, and quite high-grade; at present the Topia district is far from a railroad.

GUANAJUATO.

Three new winzes are being sunk from the deepest level of the Pinguico mine; all are in good ore.—Development is being pushed on the San Gregorio property in the La Luz district.—The smelter at Aguascalientes announces that, if the financial stringency lasts much longer, it will be unable to receive any more high-grade concentrates from Guanajuato.

Special Correspondence.

Chicago.

The Mining Congress.—Character of the Attendance.—A Review of the Work Accomplished.—The Resolutions.—The Bureau of Mines and the Geological Survey.

The tenth annual session of the American Mining Congress closed at Joplin on Saturday last. In certain particulars the meeting was unusually successful. The attendance was large and representative. While Governor Folk alone among the State executives was present, and while congressmen and senators were practically absent, all phases of mining were more or less completely represented. The promoter and stock peddler were there, but in a hopeless minority. Miners, operators, smeltermen, and millmen, official geologists and consulting engineers, mine owners, and mining lawyers, were all present. A new feature was the attendance of an earnest minority of oil men, mainly from the neighboring mid-continental oilfields. There were a few coal men, though only a few, and in general the great mining interests of the Central and Eastern States, except the lead and zinc, were unrepresented. The Congress was Western in spirit and membership, and devoted most of its energies to problems most closely related to the mining of the precious metals or to the public lands of the West. If the organization is to become truly national in scope and importance it must attract the support of a large and, as yet, uninterested group of Eastern and Central men who are concerned in coal, iron, Lake Superior copper, and the various non-metallic products. If this be done the Congress will be truly national, and as such its recommendations will have a new importance. As matters now stand the action of the Congress must be considered merely as representing the organized opinion of the Western mining States. In this light it is interesting to review its work.

A long and varied program was prepared, but not all the papers were read. Two, those of Buckley and Mitchell, were primarily of local interest. The great majority of the remainder, particularly of those actually read, dealt with Western problems. Of the special committees reporting, four dealt with essentially Western problems, smelter rates, side-line laws, protection of investors, and accidents in metalliferous mines; only one, the committee on accidents in coal mines, dealt with problems of larger interest in the East.

An informal gathering such as this expresses itself most concretely in its resolutions, and here again the same comparison holds. A resolution favoring a tariff on zinc ore was to have been expected from a meeting in Joplin. So too, perhaps, locality favored a resolution calling on Congress to remove some of the anomalies of law and regulation met by the Oklahoma oil and gas producer. The strong resolution calling for a thorough revision of the land laws and proposing temporarily that mineral title be reserved in all lands patented as non-mineral, was Western. The hearty approval given the President in his general policy of conserving the undeveloped resources of the country seems also to represent the best sentiment of the West.

The resolutions asking for a Bureau of Mines and for the expansion of the work of the Geological Survey may also be taken as thoroughly representative of Western thought. Incidentally the usual resolutions of thanks were passed and the Congress wisely concluded to abandon its general Bureau of Information and to allow no opinions or advice regarding properties to be given by any officer of the organization in his official capacity.

The main interest centred in the resolution regarding the proposed Bureau of Mines. As is well known, the Congress has worked persistently for the establishment of a Department of Mines along the lines of the Department of Agriculture and to be headed by a cabinet officer. Ten years of agitation of this sort seems not to have produced any tangible result. Considerable importance therefore attaches to the change of front indicated by the simultaneous demand for a bureau devoted exclusively to mining and for further support of the Geological Survey. The two bureaus would constitute an excellent nucleus around which a Department might later be made. It is understood that President Roosevelt will recommend the establishment of such a bureau and that the chance of seeing it established by the present Congress at Washington are unusually good. It may be noted that the re-establishment of the office of Commissioner of Mines, even with somewhat different duties, would be pleasingly reminiscent of an earlier period of American mining. If we can have a commissioner as able as R. W. Raymond was, the office will certainly justify its creation and the mining industry will be benefited.

Salt Lake, Utah.

Coinage of Silver.—A Public Movement.—Views of Solomon Guggenheim.—Effects of Smoke Decisions.—Shipments From Park City.—The Yampa Smelter.

A movement, having for its object the coinage of a large amount of silver as a means of relieving the present financial stringency throughout the country, has been inaugurated here during the past week and the Commercial Club has called a meeting of prominent citizens at which Solomon R. Guggenheim, of the American Smelting & Refining Co., will be invited to speak. In fact, the idea of silver coinage as a remedy for some of the existing financial ills was suggested by Mr. Guggenheim himself in an interview with the representatives of several Salt Lake daily papers. The smelting man believes that if the Government should immediately purchase and coin, say 50,000,000 oz. of silver and place it in circulation, it would have the effect of clearing up the situation very materially. "There are many reasons," said Mr. Guggenheim, "why such a step should prove to be a good one. To begin with, the gold supply at the present time is inadequate to cope with prevailing conditions; whereas, coined silver, having the guarantee of all the gold in the treasury at Washington behind it, would prove as good a substitute as the gold itself. In offering my opinion I have France in mind as an example of a country where such a system has been found to work well. It is a fact that there have been times when money in New York commanded interest at the rate of 50%, while in France, on the same day, the amount could have been obtained for 3%. This is by reason of the fact that France keeps a large reserve silver coinage at all times and when necessary pays this out just as it would gold. Suppose such a plan were in operation here. While in large amounts silver might prove inconvenient as a medium, yet I do not believe under the circumstances there would be as many objections as found now in the matter of the acceptance of cashiers' checks. Another point: While both the production and coinage of gold have increased in proportion to its usefulness and the country's needs, silver has not. There are now no new silver dollars being minted, and probably under ordinary circumstances none would be for some time to come. A few years ago, the production of silver was to gold in a ratio of about 23 to 1. At this time it is 8 to 1. This fact alone is an added reason in

favor of an increased silver coinage. These are perhaps the main reasons why I think such a plan would prove a good one and such men as I have spoken to along these lines heartily agree with me. The matter would, of course, have to be brought to the attention of the Government in the proper manner, and if this were done I see no reason why the plan should not be entertained. I do not wish to be understood," concluded Mr. Guggenheim, "as advocating absolute free coinage of silver."

In discussing the forthcoming meeting Secretary Fisher Harris of the Commercial Club said: "Make as emphatic as possible the statement that this movement is absolutely divorced from politics. It is absolutely free from a desire or intention to bring about free coinage of silver. The sole object is to relieve the financial stringency through the purchase and coinage of a quantity of silver bullion. It will help the West, of course, but that is a mere incident. There is no free silver and there is no politics in the movement."

There has been a great deal of talk about the United

a large percentage of iron, are in demand. The American company is taking care of some of the Goldfield and Tonopah ore under contract at its Colorado plants.

Work has commenced on the zinc plant to be erected by the Grasselli Chemical Co., at Park City. The ore to be treated will come for the present entirely from the Daly Judge mine. This company has 150,000 tons of zinc middling on the dump that will average between 15 and 20% zinc.—Ore shipments from Park City last week amounted to 1,408 tons, the contributing mines being: Silver King, 944; Daly Judge, 464 tons.

The Yampa smelter at Bingham is being warmed up again after a shut-down of about six weeks. The plant will be in full operation in about 10 days, by which time the new 12,000-ft. aerial tramway will be ready. The capacity of the plant has been raised from about 400 tons to 750 tons of ore daily. The tramway will be operated between the mine and smelter and will remove the necessity of depending on the Rio Grande Western railroad for transportation.—A new electric hoisting plant is being installed in the Humbug mine of the Uncle Sam Consolidated Mining Co., in the Tintic district.—Notwithstanding that the Colorado Mining Co., of Tintic, was requested to curtail its output for a time, the man-

Utah.

States Smelting, Refining & Mining Co. retiring from the smelting business in Utah. A statement has come from one of its chief officers to that effect, but here in Salt Lake the situation is not regarded as serious. The courts have allowed the American Smelting & Refining Co. to continue the operation of its lead smelter at Murray under a modified decree, and it is believed that some such an arrangement will be granted to the United States company. In fact, negotiations toward that end are now pending, and there is every reason to believe that they will be successful. The chances are that the copper smelter belonging to the United States company will be moved elsewhere, that is, outside the Salt Lake valley.

The management of the American Smelting & Refining Co. has taken occasion to enter a denial of its reported intention of closing either or both of its Utah smelting plants. On the contrary, both of them are running up to their furnace-capacity, and will continue to do so, with the probability of adding more furnaces. The statement has also been made that the company is not taking on any more contracts from Goldfield and other Nevada camps where silicious gold-silver ores are produced, for the reason that the company's yards have become clogged with this class of ore. Copper ores, however, that carry

Map of Southwestern Colorado.

agement has announced that its monthly dividends of \$60,000 will be continued.—The Cave silver-lead mine in Beaver county has been sold to a syndicate of Denver and Pittsburg parties. It is one of the oldest mines in the State, and is said to have produced more than a million dollars.

Denver, Colorado.

Important Engineering Work.—Prospecting in Gilpin.—Lower Rates of Treatment.—Lost Bullion Case.—Old Mines Reopened.

The Secretary of the Interior, James R. Garfield, has announced that the United States Government will construct a \$1,500,000 high-line irrigation canal beginning at the foot of Mt. Garfield and extending to the Utah line; \$50,000 has already been set aside to establish engineering headquarters at Grand Junction. The survey and the accumulation of necessary data will be begun at once. E. E. Sands, constructing engineer of the Reclamation Service, who is now supervising work on the Gunnison tunnel, will have charge of the survey. This canal will reclaim 70,000 acres of arable land in Grand Valley adjoining Grand Junction.—Prospecting and development work is being pushed ahead in Gilpin, Clear Creek,

and Boulder counties with unusual vigor. New concentrating plants are being erected at Georgetown, Silver Plume, Central City, and Eldora. The Central, Metropolitan, and McClelland tunnels are all being advanced rapidly to completion. The principal strikes of late have been silver-lead and gold ores. Owing to the scarcity of miners in the southwestern part of the State, much development work is being delayed. The work on the Cable and Shamrock mines and on the Potter tunnel has been stopped until the labor situation becomes easier. The cessation of work at many copper mines throughout the West ought to provide plenty of men for the precious-metal mines.

The low rate on low-grade ore, which the United States Reduction & Refining Co. inaugurated on October 15, is stimulating the output of Cripple Creek to a notable degree. The railroad officials cannot supply sufficient cars. Frequently 3,000 tons are shipped in a day. When the Golden Cycle mill is completed and ready to treat the ore, it is expected that a lower rate even than that now in vogue will be put in force. This will be in January. Under the present conditions, the Eagle Ore Co. of Victor has been forced to put on a night-shift to handle the increased tonnage sent to its plant for sampling.

Motion for a new trial has been filed in the United States Circuit Court by C. L. Blackman, A. E. Keables, W. B. Cameron, and others connected with the Lost Bullion Spanish Mines Co. These parties were convicted of fraud. In the indictments it was charged that no deposits containing valuable ore or any metal had been discovered on the property. The defendants now claim that since the trial they have mined 21.99 tons of ore from the property and have sold the same to the Chamberlain & Dillingham Ore Co. of Denver for \$387.55, less the sampling and treatment charges. The petition gives as evidence the names of the men who saw the ore sampled at the purchaser's plant. It is to be hoped that the defendants will be able to prove that the ore in question really came from the Lost Bullion Spanish mines. Judge Lewis will hear the motion on November 20. [The judge postponed a ruling until December 26.]

A few Colorado mining men are now preparing a petition to lay before Congress when it convenes on December 10. The petition asks that the annual assessment work on unpatented claims be suspended until the present financial crisis is passed. In 1893, owing to the stringent financial conditions prevailing at that time, Congress passed an act removing the necessity for completing the \$100 worth of work on each unpatented mining claim. An affidavit only was required from the holder stating that his intentions were good and that he would comply with the law in its usual form when the time limit expired. The next year, 1894, by a special act of Congress, the same law was continued in force another year. Again in 1897 a somewhat similar act was passed, applicable however only to those who had enlisted in military service and exempting those who owned mining claims or interests from all liabilities during their term of enlistment. The present crisis is not as bad as that of 1893. The position of the West is comparatively strong and this seems an attempt to take advantage of a relief measure when no real necessity exists.

After 15 years of idleness the Exchequer mine at Salida is being re-opened. The nearness of the smelter, good transportation facilities, and the premium allowed for the iron in the ore make it possible to prospect and develop this promising property. The Housel-Melvin Mining Co. is installing machinery on its property on the Craig placer near Steamboat Springs. The equipment consists of a 50-hp. automatic high speed engine,

two four-inch centrifugal pumps, and a 150 light dynamo. A dredge is to be put at work on the placer as soon as possible.

Wallace, Idaho.

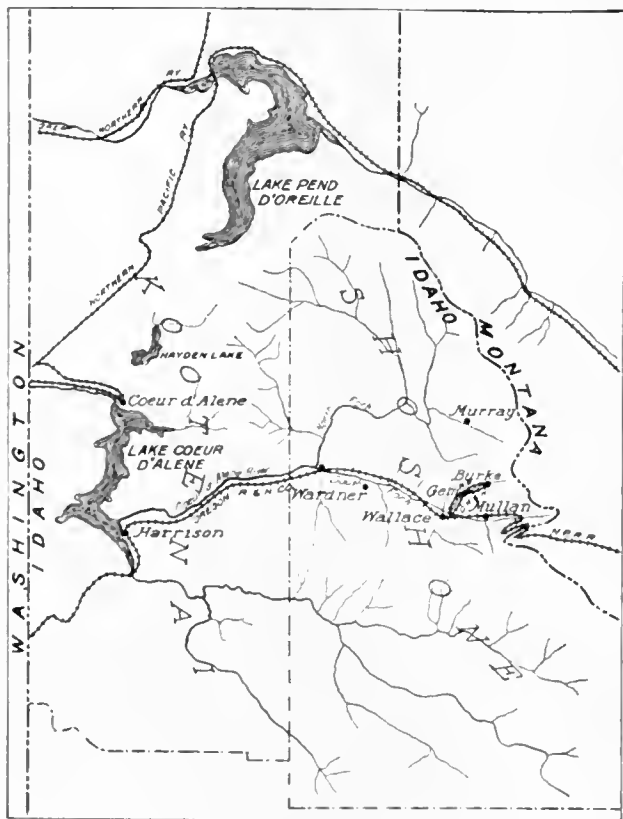

Local Conditions Better.—Strike in the Rex.—Antimonial Gold Ore.—Big Output of the Bunker Hill.—The Lookout Group.—The Monarch Mine.—Litigation Over an Assessment.

The mining industry continues to progress all through this part of the country in spite of rumors of all sorts, absurd and otherwise, and the gloom that was felt for the past week or two is rapidly clearing away. The old story of Conr d'Alene mines being reorganized at a big profit seems to have been repeated in the case of the Rex mine, 12 miles from Wallace, on the Northern Pacific railroad. An immense body of shipping galena ore has been uncovered in the lower workings. The strike was made 125 ft. below the upper adit, and when first encountered the ore was about two feet wide, but this has gradually enlarged to five or six feet. Assays of the ore show returns of from 62 to 67% lead, and as high as 51 oz. silver per ton. It is calculated that there is over \$250,000 worth of ore in reserve at present, and the extent of the orebody still remains undetermined. The mill, which will have a capacity of about 250 tons of ore daily, will be started immediately, employing 21 men, while 35 will be employed at the mine. Over \$1,000,000 worth of ore was shipped from this mine in 1887.

No less than 1,154 tons of lead-silver ore were passed through the Kellogg adit of the Bunker Hill & Sullivan mine at Wardner yesterday. This is the second greatest lead mine in the world and this output of ore comes within a few tons of breaking all previous local records. The mine has paid nearly \$10,000,000 in dividends.—Some fine ore has been encountered on the property of the Clearwater Copper & Gold Co. in the Clearwater district. Samples brought to Wallace assay all the way from 14 to 33% copper, from 3 to 21 oz. silver, and from \$1 to \$1.80 in gold per ton. Over 200 tons of this ore has been taken from the No. 3 tunnel in 26 days. The ore is self-fluxing and there is some talk of erecting a smelter at the property.—The Gettysburg mine, near Mullan, has closed down and will not resume until the spring. Up to today the mine had been employing three shifts of men and an excellent showing had been made.—Work has been resumed on the Lookout group of claims in the Mullan district. The property has been closed down for about six months and it will be managed in future by D. C. Hessian. Over 860 ft. of work has already been done and at present operations will be confined to driving on the vein from the end of the 700-ft. tunnel toward the discovery shaft, where a splendid showing of galena ore and carbonates has been made. The drift will be continued to a point directly underneath the shaft, at which point a vertical depth of 400 ft. will be available. No assays have been made from the lower workings, but the surface ore assays from \$5 to \$40 per ton.—The lower adit on the Copper Queen property near Mullan has now cross-cut 16 ft. of the lode without disclosing any sign of the hanging wall, and the whole of the face is now in chalcopryite and peacock copper ore averaging as high as 20% copper. Much of this ore is clean enough to sort by hand and ship without concentration. The gangue is spathic iron. In the upper level the lode showed a width of 40 ft., and it is hoped that the new level will put the mine on a shipping basis, as the drift is over 100 ft. east of the body of solid ore disclosed by the winze from the upper tunnel.—Between 400,000 and 500,000 tons of free-milling gold ore is said to be exposed in the Monarch, just across the State line and situated at

DeBorgia, Mont. The mine has just been inspected by E. D. Sanders, of Spokane, with a view to a purchase. This property is equipped with a 5-stamp mill, sawmill, and all the other accessories.

Some excellent ore has been taken from the Ben Hur mine in the Saltese district. This was taken from an open-cut and not more than 12 ft. from the surface. It is chloride and the silver contents are high. The assay shows \$1.20 in gold, \$25.92 silver, and \$17.64 in copper. The ore is taken from the lode from which the Last Chance Co. of Wardner has shipped so much rich ore. About 10 inches of 30% lead ore has been encountered at about 225 ft. in the adit of the Phedora mine in this district. The ore has just been encountered and the body is improving with every shot.—Thomas Wall, one of stockholders in the Basin Mining Co. has brought action against the company to prevent the sale of 20,000 shares on which an assessment has not been paid. Wall claims

The Coeur d'Alene, Idaho.

that the company has refused many offers of 10c. per share for its treasury stock, but refuses to sell for less than 15, and, rather than accept the smaller price, levied an assessment for the purpose of continuing the development work. The company, on the other hand, claims that they are quite within their rights in making an assessment, and that every legal formality has been complied with. The case is an interesting one.

The Hecla Mining Co. at Burke has declared its 53rd dividend. This is at the rate of two cents per share and the total amount involved is \$20,000. For this year \$460,000 has been disbursed and a grand total of \$1,460,000 has been paid by the company.—An assessment of two mills per share has been levied on the capital stock of the Sonora Mining Co. E. O. Herring, of Wallace, has been appointed to fill the vacancy caused by the resignation of C. W. Gibbs, the secretary-treasurer of this company.—At a special meeting of the Hector Mining Co. options were taken on the Ontario claim and on one-half of the Lucky Boy lodes extending over a period of 18 months. The claims adjoin the company's property at Burke.

Butte, Montana.

Boston & Montana Operations.—The Orebodies in the Mountain View.—The Pennsylvania and Leonard.—Fighting the Fire Underground.—Systematic Plans.—British Butte Co.—A Supposed Rich Gravel Deposit.

Since production was decreased, the Boston & Montana Co. has employed 1,450 men, but 385 of them have been engaged in fighting the fire in the Leonard and West Colusa workings. The others are employed at the Mountain View, Pennsylvania, and East Colusa. The company has been shipping as high as 1,100 tons of ore per day, that is, 600 from the Mountain View, 400 from the Pennsylvania, and 100 from the East Colusa. The Mountain View is unquestionably the biggest copper mine in the Butte district. The veins—six in number and running from 8 to 50 ft. in width—have been developed to a depth of 1,400 ft., and some ore is coming from every level. The shaft is 2,200 ft. deep and has been connected at that depth with the 2,200 of the High Ore mine, of the Anaconda Co., for drainage. The Mountain View is capable of yielding almost any grade of ore, but the average of first and second class is about 5% copper. At the Pennsylvania, mining is confined to the workings above the 600-ft. level, on the old veins. Below the 600 the Butte Coalition Co. is interested in the orebodies, owning 38% and the Boston & Montana 62%, and when the Coalition practically shut-down, work in that portion of the Pennsylvania was stopped. The veins have been opened to the depth of 1,400 ft. there and some large and rich ore has been blocked out and was being mined when the order for suspension was given. The Leonard has also been worked to a depth of 1,400 ft. and the West Colusa to a depth of 1,800 ft. At the Leonard the company is installing an auxiliary pump, having a capacity of 100 gal. Since the fight with the fire began the water to be pumped out has about doubled, and it brings up some rich copper solution from which the copper is recovered by precipitation, and the company's precipitation business has consequently increased greatly. The East Colusa is being worked to a depth of 900 ft., and the Boston & Montana was about to start sinking to the 1,200 when all development work was ordered discontinued. A large new orebody was opened under the East Colusa shaft from the Leonard workings.

The Boston & Montana is making good headway with its fire-fighting work in the Leonard and West Colusa, and conditions in those mines are immensely improved. Within a month the Mitchell air-shaft, which is being sunk right over the fire on what is known as 'the neck,' near the corner of the Minnie Healey claim, will be completed, and all the gas and smoke from the fire will be forced up that shaft. It is now 800 ft. deep and will be sunk 900. That it is very near the fire has been proved by the intense heat encountered recently. When that shaft is completed the fire will be attacked from all sides. The company is sinking four shafts for the purpose of fighting the fire. The old Gambetta No. 1 shaft, 150 ft. east of the Mitchell, is being re-timbered and sunk deeper. It is now 300 ft. deep. Gambetta No. 2, about 150 ft. farther east, is 200 ft. deep. Farther east yet is the Minnie Healey shaft with a depth of 1,200 ft., to which 200 ft. were added by a raise made by the Boston & Montana from the Leonard workings. The Minnie Healey had served as a vent for the gas from the fire, but recently it caved all the way down and shut off the draft. The Boston & Montana is now engaged in re-opening and re-timbering that shaft. In addition to these four shafts the company has also obtained permission from the Butte Montana Co. to use the shaft of the Alex. Scott mine and is making connections from that shaft with the West Colusa work-

ings. Connections have already been made at the 700 and 900 levels, and work is now being done on the 1,000-ft. level. The Butte Montana Co. sunk its shaft 1,000 ft. deep, and the Boston & Montana has agreed to sink it 200 ft. deeper, and from the bottom the final connection with the West Colusa workings will be made by the Boston & Montana Co., which will give splendid ventilation to both properties and save the Butte Montana Co. a large expenditure for development work. In the opinion of J. C. Adams, general superintendent of the Boston & Montana Co., the fire in the mines will be under control in a short time now. Of course, the fire stopped all work in the Leonard, West Colusa, and Gambetta ground, and also put a temporary end to all development work that had been under way in those properties. It is fortunate that the enforced suspension came during the general copper depression.

The British Butte company, which is engaged in exploring placer ground west of Butte, has its shaft down 680 ft., and from the bottom of it the company has been boring with a Keystone drill to a depth of 850 ft., and some good gravel has been brought up, assays running as high as \$11 per cu. yd. Bedrock is not yet within reach. The water is so heavy that sinking is carried on with difficulty, although a large pump is in operation at the 680-ft. station. Samples of the stuff being brought up by the drill are taken every few feet, and the increase in value has been gradual. At a depth of 833 ft. the assay gave \$1.20 per ton per cu. yd., which increased to \$11 at a depth of 850 ft. All the samples show some gold. Some of the dirt recently brought up carried small nuggets of gold, and this accounts for the high assays. It is the intention of the company to cut another station at the 850 and to run some levels from that point and drift along the channel. It has been the object of the company to sink to bedrock, the theory of geologists being that the country west of Butte, upon which the British Butte claims are situated, was an old lake-bottom and that at bedrock great placer gold deposits would be found. Charles Olden, an English engineer, who represents the London men interested in the company, has endorsed that opinion and he expresses the belief that an immense area of pay-dirt will be opened. It has been demonstrated that the gold can be saved by means of the cyanide process, and an experimental mill has been built on the ground and is in charge of H. L. Whitaker, a metallurgist sent out from London.

Chihuahua, Mexico.

The Parral District.—Veta Colorada Mines.—Shipments to Smelters.

—Mina Prieta.—The Famous Palmilla.—Operations at Santa Barbara.—The Hinds Consolidated.—The Tecolotes Mill.

There are two classes of ore in the Parral district, namely, the clean silicious ores which are now considered susceptible to cyanide treatment; and the heavy zinc-lead sulphides which will require concentration. The first of these carry silver as chloride, sulphide, and bromide. These ores will run about 84% silica, 2% iron, 1½% sulphur, and 18 to 24 oz. silver per ton. The mines of the Vita Colorada Mining & Smelting Co., near Parral, have extensive bodies of this highly silicious class of ore, and to extract their silver contents a cyanide plant is being erected under the supervision of Robert Allen. The line of the Parral & Durango railroad runs from Parral to Minas Nuevas station, the latter being situated near the Vita Colorada mines. Tests indicate that an 80% extraction can be made by cyanidation. The heavy sulphides of the Parral district are estimated to carry an average of 18 oz. silver, 10% lead, 15% zinc, and about 0.08 oz. gold per ton. These sulphides are found

at and below water-level, but this level occurs at a variable depth. While the output of the better grade ore is curtailed just now, ordinarily the shipments of Parral and Santa Barbara ores to the Torreon smelter run from 1,500 to 1,800 tons per month. The Torreon smelter is represented in the district by James W. Hambleton. The Monterrey Mining, Smelting & Refining Co., represented here by Adolf Beyer, has contracts that call for a large tonnage from the Parral district. The high-grade shipments from the Palmilla go to the Monterrey plant. It is claimed that ordinarily the shipments from this district to the Monterrey plant will run 2,500 tons per month, and this is largely silicious ore. The American Smelting & Refining Co. is represented at Parral by Ferguson Doak. This company handles the ore and concentrate of the Hinds Con. M. Co., the Minas Tecolotes, and Granadefia of Santa Barbara. The Mapimi smelter, situated some 35 miles north of Torreon, also obtains ore from the Parral-Santa Barbara district.

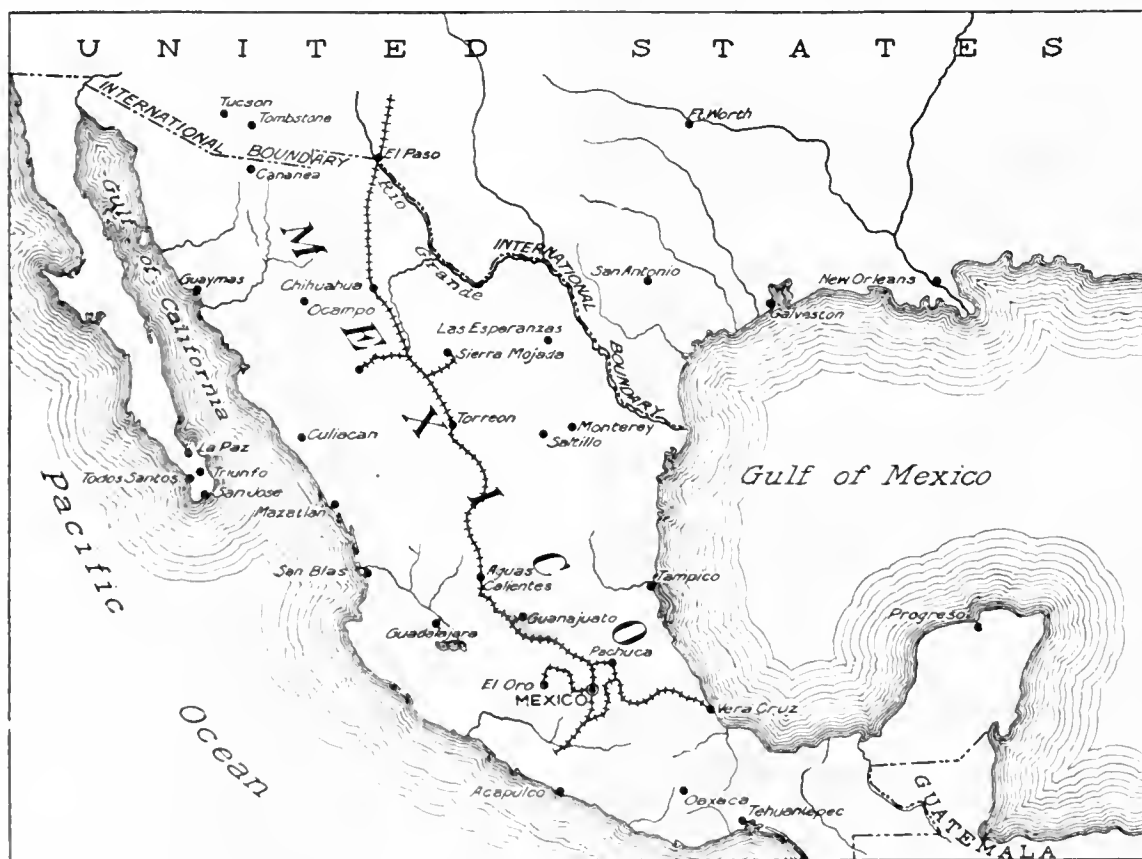

The Mina Prieta, belonging to the Prieta Consolidated Mining Co., is said to be the oldest mine in this district, excepting the Clarinos at Santa Barbara. The Prieta has a three-compartment shaft 400 ft. deep. Its hoist, air-compressor, and crusher are operated by electric power, as is also a locomotive used in hauling ore from the shaft to the railroad. The water-level is at 300 ft. depth and the ores above it were worked out long ago. Below this level, where present development is in progress, the ores are said to run 10% lead, 10% zinc, and 30 to 150 oz. silver per ton, with 2 to 4% copper. An adit is being driven from one of the upper streets of Parral to the shaft to be used as a drainage channel. This will reduce the lift required of the pumps about 175 ft. D. H. Bradley is manager of the property. The El Tajo mine, being managed by E. A. Swain, is on the same vein as the Prieta. About 1,000 tons per month is being mined.

The Perros Bravos mine, near Santa Barbara, is under lease to Butler & Cooper of Parral, who are mining and operating a jigging plant. They have been shipping concentrates since last March. Their ores are said to carry an average of 5 grams gold, 850 grams silver, 10% lead, and 6½% copper. The gangue runs about 50% silica, 8% iron, 6% zinc, and 7% lime.

The Palmilla mine, situated four miles from Parral, whose production since 1900 brought great wealth to Pedro Alvarado, is now under a 15-year lease to J. A. Coram and associates and is under the general management of F. C. Morehouse. An aerial tramway connects the mine with the ore-bins on the railroad. The main working shaft is down to a depth of 575 ft. on the principal vein of the group. The bottom of the shaft is at water-level, and the lowest workings form a sump in which a quantity of water has accumulated. There is a pump station on the 500-ft. level and one at the 550, electrically driven pumps being installed at each of these. A drainage adit is being driven from the side of the hill to cut into the shaft at a point 250 ft. below the collar, thus making it necessary to pump water up to that level only. Two new air-compressors are being installed, to be electrically driven. Underground the workings expose great chambers, showing the orebodies to have been 100 to 200 ft. wide. The ore is silicious, carrying sulphide of silver, chlorides, and native silver. At water-level the ore becomes more of a sulphide, and the lessees intend to sink deep into this sulphide body, the showing at the bottom of the workings indicating that the width of ore is just as great below present workings as it was in the worked-out chambers above. Pumping facilities are now ample for keeping the water out of the way. A. L. Dickerman, consulting engineer of the property, is at the mine.

The Hinds Consolidated Mining Co. is developing and mining a group of five properties, situated three miles north of Santa Barbara. These include the Remedios, Reforma, Santa Gertrudis, Clarines, and Pilaes, all of which are on one and the same mineral vein, whose outcrop is traced 7,000 ft. The vein will average 10 ft. in width, as demonstrated by the large amount of work performed, and strikes north-south through a shale country. The gangue is a quartz carrying lead and silver, associated with which are gold and copper. In some parts a little zinc occurs, but in the concentrating process to be adopted a sufficient part of the zinc can be eliminated to obviate any penalty at the smelters. In the Clarines there are some lead and copper carbonates. The mines are opened by both shafts and adits, the latter being on the vein. The greatest depth is 350 ft., in the Remedios. A concentrating mill of 200 tons capacity is

driven 1,900 ft. on the strike of the main vein, with branches running from it on the two secondary veins. This level is equipped with electric haulage. Other levels open the same veins above this one, and near the portal of the main level a shaft goes down 300 ft., from which drifts have been extended into the ore. There is a vertical distance of 800 ft. between the highest and lowest workings. These veins stand nearly vertically between slate walls. The ore is complex, being a sulphide, carrying gold, silver, lead, zinc, and copper. A visit to one of the stopes showed a vein of solid ore 10 to 15 ft. wide. It is said 150,000 tons of ore are broken in the mine at present. The mill of the Tecolotes is near the town of Santa Barbara. It makes an output of 600 tons per day. The mill treatment includes crushing, classifying, and concentration by jigs, tables, and vanners. The 28 sets of jigs make a pro-

Map of Mexico.

being erected, which is expected to be in operation in January next. This is to be the first of two units, the second to be erected at a later date. The new mill provides for coarse concentrating with jigs, classifiers, and tables. The power is to be steam, with wood as fuel. High-grade ore and hand-jig concentrate, amounting to one car per day, are being shipped. There are 20 hand-jigs in use here, producing a high-grade concentrate. A railroad branch, over three miles in length, has been completed from the Mexican Central tracks up to the millsite, and material is being hauled by a new locomotive. Wm. Wells Elmer is general manager for the company, the president, Howell Hinds, having other mining interests in various parts of Mexico and the United States.

The Minas Tecolotes at Santa Barbara belongs to the American Smelter Securities Co. of New York. At this property A. B. Emery is general manager; W. M. Drury mill superintendent, with E. E. McIntire as mine superintendent. The mine has one principal vein, with two feeders coming into it at an acute angle. A level has been

duct of five sizes. The jig tailing is reground in Huntington mills; part of the jig-tailing, however, is reground in rolls.

The reground material passes through Richards' classifiers, the first size going to jigs and the second to Wilfley tables. The overflow from the classifiers passes to the vanners, as does also the thickened pulp. The jigs make a product that is largely lead; the Wilfley tables make a lead-iron product, also a zinc middling; to treat the latter a new plant is being built, in which magnetic separators are to be installed. The silver and gold are associated with the lead and iron in the table and vanner products. There is a large accumulation of zinc middling here to treat which the new zinc plant is being erected. A gas-producer supplies a wood and coal gas to operate seven American-Crossley gas-engines, the latter in turn operating seven electric generators. Two of the latter are direct connected to two Nordberg air-compressors. The other generators drive motors throughout the mill and shops. A steam railroad is operated to haul ore from the mine to the mill.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ON several New Zealand dredges shaking screens have been installed in place of revolving trommels.

SORTING at the Rand mines varies considerably in amount; at the Princess Estate mine 37% of the mine-run rock is sorted out, while at the Consolidated Langlaagte mine no sorting is done.

ONE machine sharpener at the Homestake mine, South Dakota, is sharpening steel for 100 drills with less waste of steel and about one-tenth the number of broken bits to trim as there were when hand sharpening was employed.

THE Adair-Usher cyanide process is rapidly increasing in favor on the Rand. It is already in use at the Crown Reef, Ferreira, Geldenhuis Deep, and May Consolidated properties and is being installed at the New Princess, Ginsberg, and Treasury mines.

THE WORKING COSTS per ton at the Great Boulder Perseverance mine, in the East Coolgardie district, West Australia, are as follows: Ore breaking, \$1.63; sulphide treatment, \$3.07; general expense, \$0.27; tailing distribution, \$0.12; total cost, \$5.09.

THE COST OF CYANIDATION at the Progress mine, Reef-ton, New Zealand, was 39c. per ton, made up as follows: Wages, per ton, 10c.; cyanide, 21c.; zinc and chemicals, 4c.; general stores, 1c.; assaying, 3c. The Progress mill contains 65 stamps; 38,410 tons, 68.4% of the tonnage crushed was cyanided.

DEVELOPMENT WORK in wet mines should be kept at least one level ahead of stoping. This policy keeps the stopes in a better drained condition than when, in a wet mine, ore is stoped from the deepest level. All water should be caught in drains, as soon as it can be, and should not be allowed to seep down through the stopes. Especially is this true in copper mines.

IN CYANIDING ANTIMONIAL GOLD ORES sodium cyanide seems to be more economical and more efficient than potassium cyanide; at least that is the case at the Keep-it-Dark mine, Reefton, New Zealand, where the use of sodium in place of potassium cyanide has decreased the cost of cyanidation 12 cents per ton. The total cost per ton for cyanidation at this property is 66 cents.

THE working costs at Rhodesian mines, as taken from the reports of companies whose combined output amounts to 752,478 tons (over half the output of Rhodesia) are as follows: Stoping, crushing, transporting, sorting, etc., \$1.75 per ton; milling, 95c.; general expenses, 65c.; cyaniding (177,846 tons), 33c.; total working expense, exclusive of redemption, \$3.68 per ton. On producing mines, the number of white men employed per stamp averages 1.17 and the number of natives averages 17.33.

AS TO METAL-PRESERVERS, several kinds of paint have been used with varying success, but the best results have been attained with the use of red lead mixed with linseed oil. The steel should be thoroughly cleaned and one or two coats of this paint applied. Care must be taken to rub the first coat firmly and uniformly on to the metal when it is dry, leaving no pores unfilled, as the perspira-

tion of the metal will work out on such places and rust will appear. After having established a good base of red lead paint, two coats of any good paint can be applied.

DRILL-SHARPENING BY HAND at the Homestake mine, South Dakota, costs over twice as much as machine sharpening. To sharpen 1,000 drills it takes 10 blacksmiths at \$3.50 and 10 helpers at \$3, amounting to \$65, and it requires 1,200 lb. of black coal, costing \$7.20, making a total cost of \$72.20. The cost of sharpening 1,000 drills by machine is as follows: One machine, air to run same, \$2; 2 blacksmiths at \$3.50, 2 helpers at \$3, \$13; 2 blacksmiths sharpening block-hole steel, \$7; 2 extra tool packers, \$6; 720 lb. coke, \$4.75; fire-brick to repair furnace, \$0.20; total, \$32.95.

THE cost of shaft-sinking on the Rand, when machines are used, is \$2.80 per ton of rock broken; when hand-drilling is used, the cost is only \$2.30 per ton. In driving drifts hand-drilling is also cheaper, but in stoping, when machine-drilling is used, the cost is about 30c. per ton cheaper than when hand-drilling is used. On the Rand 88% of the development work is done with machines, owing to the greater speed obtained, while only 47.8% of the ore mined in the stopes is drilled with machines. This is due to the decrease in the grade of ore hoisted, when machines are used in narrow stopes.

CROSS-HEADS should always be used when hoisting is done by means of buckets. In sinking a shaft, many favor the use of a bucket instead of a skip. The sinking-skip with its long runners is far from ideal but, in large and deep shafts, hoisting with skips is not only safer but somewhat more economical than hoisting with buckets. When sinking a shaft in which hoisting is being done, a bar of ground 10 ft. thick at the bottom station is far safer than the more commonly used wooden bulk-head. Through this bar only the hoisting compartment is cut. Buckets, of course, are used in sinking from an underground level; a cross-head should always be used in such work.

HELMETS for fighting underground fires should be always provided at large mines. At Butte, Mont., such is generally the case. Coal mines almost always are so equipped, but metal mines are generally considered immune from underground fires. But that is far from the case, especially at mines whose ore carries a heavy percentage of sulphur. The recent experience at Bisbee, where the sudden breaking out of a fire in an abandoned stope threatened to restrict the work in several of the large properties, is a case in point. Fire-fighting equipment for underground use is seldom needed, but when required it is wanted badly. Ability to safely build bulkheads near the fire frequently is very valuable. A good helmet makes that possible.

MANY copper mines in the United States have greatly decreased their force of miners; consequently in many districts of the West there is an over-abundance of miners—quite a contrast to conditions last summer. Already many mining men have noticed the increase in the amount of work which miners think constitutes a shift's work now that many miners are 'rustling' for jobs. We hope that this will emphasize the fact that any man does more work when he knows there is another man anxious for his job. But financial depression is not necessary to produce this condition. By properly ventilating the stopes, by furnishing the miners with plenty of good tools, by providing good bunk-houses at mines away from towns, and in many other ways, it is possible to accomplish this even in prosperous times.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanidation in Nevada.

The Editor:

Sir—Although a great deal has been written regarding the mines of Goldfield and the surrounding districts, comparatively little has appeared in print regarding the treatment of the ores produced by these mines. The article by A. R. Parsons (in your issue of October 19) is a notable exception.

In looking over the list of mills operating in these districts, it is interesting to note that the predominating scheme of treatment is wet crushing and cyaniding; amalgamation, concentration, and re-grinding forming details of the general plan of treatment. The idea seems to prevail that this is the only process suitable for these ores. Engineers know how difficult it is to introduce a new process into a district where certain methods have come to be recognized as standard, even though the proposed process has been highly successful elsewhere. Having this in mind, and desiring to overcome these objections, I propose a discussion on the subject of the best method of treating the sulphide and sulpho-telluride ores of Goldfield. The ores of Tonopah differ from those of Goldfield in one important particular—the presence of silver—and it would probably be best not to consider these, at least for the present.

By "best" method is meant that one which yields the greatest ultimate profit. The following is a provisional description of the Goldfield ore: The ore is a hard white quartz averaging about 85% silica, 7% pyrite, and about 8% lime, magnesia, and alumina, the latter being derived from the wall-rocks. The ore carries about 3 oz. gold and no silver. The gold is in a fine state of division and does not readily plate. The sulphides are very fine and uniformly disseminated through the rock. The assay-value of the sulphides runs from \$400 up. Tellurides of gold are frequently present.

For this ore I propose the following scheme of treatment: Preliminary crushing in breakers and roughing rolls and fine crushing to 25 or 30 mesh in ball-mills after drying. Oxidizing roasting in Edwards furnaces and final leaching with cyanide solution. The details might have to be changed so as to include re-grinding and amalgamation after roasting, in which case separate treatment must be provided for the sand and slime. I have not attempted to go into the details of the above plan as they can be best brought out later on.

I would suggest that the process now in operation be designated as the Nevada Wet Process and the proposed one as the Nevada Roasting Process. There is nothing so original in either as to warrant such distinctive names, but it is convenient for the purposes of discussion.

R. STUART BROWNE.

San Francisco, November 18.

A Sampler.

The Editor:

Sir—Referring to your issue of November 9, I would advise Mr. Knight, who is having trouble with his sand-sampling augers, to try one made as follows: Take an ordinary thin brass vanner roller, saw off each end, thus making a hollow tube. Take a piece of half-inch pipe, put on one end a bushing of a diameter slightly less than the inside of the tube, fasten a piece of wood about five inches long to the larger end of the bushing; the whole becomes a ramrod to work easily in the tube. To use it,

place one end of the tube with the ramrod in the sand, place the other end under the arm-pit and press down as convenient, withdraw, and ram out the charge; place the tube back in the hole and repeat the performance until bottom is reached. For very wet slimy material, the rod should be rammed up and down once or twice to produce a suction effect. This method of sampling requires a little longer time than with the auger, but it gives a perfect core. Samples from different depths of charge can easily be obtained.

Blair, Nevada, November 17.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 12.—Editor.]

The Editor:

Sir—I have read with mixed feelings the letters appearing in your discussion columns under the head of 'Professional Customs,' dealing with certain questions from the point of view of professional ethics.

I deprecate the attitude maintained, and the more so as some exponents have seemed to deal with the matter with, perhaps, insufficient thought. To whose benefit, I would ask, does such a discussion redound? Do we need to be told that the profession demands all that is of common sense, all that is of honesty, even to the sacrifice of individual interests, or, in the mind of the original questioner, did there lurk the idea that certain perquisites were permissible, certain latitudes to be demanded, and the sooner the general public was made aware of the privileges of a mining engineer, the better? Shall we form a union to have these points the better understood, or shall we not rather accept the watchword recently given us, "Whatsoever things are just, whatsoever things are of good report, think on these things."

I am not making an original remark, but, in my opinion, repeating a very true one when I say that a mining engineer, young or otherwise, who needs to have his conscience or his judgment upheld by 'customs' is hardly likely to appreciate the high aims that the profession demands.

N.

Nelson, B. C., November 9.

The Editor:

Sir—It appears to me that the questions may be separated into two groups; first, those of business methods, concerning which a decision can be reached by considering which course will give the most satisfaction to all concerned, consistent with thorough and honest work; second, those of business ethics in which the moral faculties should be exercised. Judgment concerning the first would vary with experience and would be based upon the nature of the work and the disposition of the client, but there should be unanimity of opinion upon those of the second group. I should say that questions, 1, 2, 3, 4, 5 (except 'c'), 6, and 9 are questions of business judgment; the remaining, 5c, 7, 8, and 10 are ethical in nature.

1. In the business of examining mines, an engineer comes into contact with two classes of people; those acquainted with the nature of the business, and those more or less ignorant of it. It has been my experience that those clients unacquainted with the business, prefer to have the work done for a fee. It is almost always possible to arrive at a fairly close estimate of the amount of time required for the work, and the fee may be based upon this. Those familiar with the business generally prefer to engage an engineer upon a time-basis.

2. In general, it is well to ask the client to acknowl-

edge receipt of a letter containing the basis of contract. No serious client will object to this.

3. A sum sufficient to cover expenses may be asked in advance.

4. An examining engineer is supposed to have a complete equipment at his disposal, including instruments, etc., as well as clothes for most climates and conditions. Any unique equipment should be supplied by the client.

5a. Personal expenses, such as laundry bills, tobacco, and ordinary medicines, should be borne by the engineer. A tip is given in appreciation of a service, and, where this service is personal, it should be paid by the engineer; when performed in the interest of the client, by him.

b. Few clients would respect an engineer who chose to travel second class.

c. This is a question in ethics. It is no more right to charge for something not received in this case, than to charge for ten days time, when the work required only a week by working in the evenings.

d. Keep the expense account to satisfy the client. To be sure, keep a detailed account of all expenses.

e. Take vouchers for everything not connected with traveling expenses.

f. Yes.

g. It is generally satisfactory to all concerned, to submit an expense account at the end of the work.

6. In general, make no report except upon positive final judgment.

7. This is a question in ethics. The information gained in examination work belongs strictly to the client, and an engineer doing examination work solely, or largely, should leave the stock market alone. The lack of thought on this subject has wrecked the careers of too many engineers, both in personal happiness and in professional success.

8. It is legitimate and advisable to see as much of a district as possible, but not to use the information for personal gain, unless with the consent of the client after a thorough understanding of the situation.

9. A client will seldom object to this, provided the facts given have a scientific rather than a practical interest, though consent should be obtained in every instance. Under most conditions a free interchange of opinion on the scientific phases of mining engineering is to the best interest of everyone.

10. If an engineer's opinion may be expressed in one word, "No" or "Yes," he should, by all means, so express it. Failure to do so, where desired, generally indicates the lack of positive conviction. Some classes of work, such as consultation with reference to development, do not permit such definite answers, and the opinion must be qualified.

It is my opinion that a habit of forming definite ideas and therefore, of reaching definite conclusions, though it cannot always be done, is worth cultivating. I have noticed that many engineers, living in a camp, grow accustomed to seeing prospects on every hillside, and become careless in examining them. If it were kept in mind that no prospect should be passed without making some definite observation, or observations, if possible, we would soon come to recognize associations the lack of knowledge concerning which largely explains the primitive condition of the science of ore deposition, compared to other branches of applied science.

In general, with reference to the questions of business judgment, it can be said: Satisfy your client in every way, consistent with thorough and honest work. As to those of an ethical nature, satisfy yourself, but study carefully your own moral decisions.

FOSTER HEWETT.

Pittsburg, November 12.

The Editor :

Sir—Discussion of the questions of T. S. in your issue of October 5 raises the whole question of the relations between examining engineer and client. Necessarily the conditions and the personalities must alter and govern each case, and no hard and fast rule can be laid down. Our profession is not like that of medicine, and a strict code of ethics does not govern us, nor is there an established or even customary rate of charges for specific services. The young engineer of mines is without protection in the way of a union or association, and therefore must hustle for himself and accept many a knock.

I shall group questions 1, 2, and 3. It is usually better to charge a *per diem* rate, but in a case where the trip may occupy several months, a monthly rate could be substituted. In the case of a short trip, say, covering a few days only, where the *per diem* rate would be insignificant and hardly commensurate with the responsibilities undertaken by a reputable engineer in a signed report, it would be better to charge a lump sum and expenses. An advance of cash to cover expenses is usual and proper, as is also the exchange of letters covering the question of the consideration, etc. Often an engineer is requested by wire to make a trip and naturally he must choose to accept such engagement as sufficient and put up his own expenses or decline the service. I have known engineers to send their reports to clients with bill attached C. O. D. by express. Also I know by experience that sometimes a report is simply ignored and never paid for, possibly because it is unfavorable or because of money stringency. The engineer does not like to sue for collection of such an account and in such a case he loses his time and often his expenses as well.

No. 4. Equipment consumed in the work, such as ore-sacks, etc., is of course chargeable; the engineer's tools should belong to him.

No. 5. Traveling expenses include all tips, as these are part of the hotel bills. Drinks, tobacco, ammunition, etc., I should say, were not chargeable. Travel first-class always. The people met on trains and steamers are a valuable source of information to the engineer. To go second-class and charge for first is not right. Keep close account of expenses and pocket any loss arising from a lapse in this line rather than introduce a large incidental list. It looks careless, and that is a grave mistake for an engineer. Make your returns at the end of the trip with your report, unless by previous arrangement.

No. 6. Make your report when the examination is completed, unless preliminary statements are requested. In making such, be careful that they do not mislead; a first impression often is a wrong one, and I have a case in mind where such a preliminary report was cabled to London and was favorable, whereas the final findings were the reverse; the result, naturally, was injurious to the engineer's reputation.

No. 7 and 8. These open up the whole field of the business of engineering. The engineer making an examination of a property should give no intimation of his findings to others than his employers and to purchase the shares of the company would be advertising his favorable opinion, by inference, at least. Also it would be held as having an influence upon his findings of fact and thus detract from the value of the report. If the engineer is in the permanent employ of a company, the matter is different. It is well known, or, I might better say, "well believed" (as our knowledge of the matter is nil), that many of the greatest lights of the mining profession made their large fortunes through speculation in shares of their own and adjoining companies. It is a further fact, and an unfortunate one, perhaps, that the business world

gauges their eminence as engineers by the light of their affluence, pays them immense fees and retainers, and considers their judgment as incontestable. The engineer deals with business men whose code of ethics is an elastic one, they demand results and they take no umbrage at the endeavor of even a poor engineer to acquire a competency. I believe it is permissible and entirely honest for the engineer to purchase stock in the properties he has examined; but he should do this with the knowledge and consent of the officials or of the parties employing him. What better endorsement should a business man want than the fact that his engineer desired to become a stockholder? Of course, I am not thinking of the common promoter who wants a report only as a kite to raise his worthless stock, and such participation by the engineer is, of course, to be deplored.

The question might be reversed by asking whether an engineer should be barred from buying a good stock because his examination and personal knowledge shows it to be good? This would place him in the position of being forced to buy stock only in something about which he knows nothing.

No. 8. If an engineer's examination shows him that the property adjoining is of considerable value, this information belongs in the report first. If the employer does not desire the additional property, after receiving the advice to acquire it, it would be folly to expect the engineer to allow the opportunity to pass, and be grasped by others; regardless of the fact that his information was gained while employed in making said report. Common horse sense and honesty will govern the engineer and in the long run carry him through all right.

No. 9. After the report is delivered and with the employer's consent, a general description may be published and would often be of value to the profession.

No. 10. Say "Yes" and "No," or say "I don't know." That's what an engineer is hired for, and he is entitled to say the last when the conditions are such as to leave the matter obscure. It is no crime to say "I don't know." Naturally the conditions must be minutely described to justify these three words, and among these conditions are workings inaccessible through caving, filling, or water. Expenses for the opening of such are only justified after consulting employers, as they should usually be borne by the owner of the property.

JAS. W. NEILL.

On the train, November 5.

Assessment Work.

The Editor:

Sir—Behold, the peripatetic locator of mining claims is to the fore again. He has located many claims, which he ought not to have done, and he has left undone the work of assessment which he ought to have done, and now at the thought that he may have to do that work himself, there is no health in him! His little flim-flam game is done, for the nonce, for pockets are out, and he is up against the ignoble necessity of working for himself unless Uncle Sam will let him off. *Mine ille lacrimae!* But Peripatetic was the same yesterday that he is today, and he will remain the same forever. At Nome, in the first few years after the discoveries were made, his locations covered miles and miles up and down the river and its tributaries, in fact all the available mining ground. And he did his hard work in the saloons, in the gambling halls, and in the dives. If a *bona fide* prospector chanced to find something good in his preserves, he at once pounced upon him. Failing to persuade him to disgorge, the gang drove him off, for, like wolves, all of that ilk band together in pursuit of the common game—the luckless wight who delves and discovers. The scene,

only, is changed; now it is Goldfield and thereabouts; but the Peripatetics are the same in type as those who held the golden sands of Nome under tribute in the latter part of the last and the early years of this century.

Neither in Nevada, nor in California, nor elsewhere is the honest miner seeking any relief from the obligation imposed upon him by law to keep his location good. He has done his annual work, or is doing it, and is too busy in his mine to spare the time to write a protest against the misrepresentation that is being practiced against him; therefore, I speak for him to expose the imposture that is being thrust forward in his name. There is not the slightest *vraisemblance!* The woe-begone hand-wringing figure that is being pushed to the front is not honest, nor is he a miner; he is a mere locator, a claim grabber of whom to beware! he is a promoter of the flotsam and jetsam type peculiar to all new mining regions! he is a speculator in mining claims, whose holdings are in groups and are rated by the quarter section or more, and he never swung a pick or handled a shovel in his life.

EDWARD A. BELCHER.

San Francisco, November 25.

The Editor:

Sir—As an admirer of the usually sound arguments found in your bright and entertaining columns in furtherance of the interests of mining, I believe it could not have been your mind or heart that was responsible for the editorial conclusions in your issue November 16, concerning the desirability or otherwise of the proposed petition to Congress to omit the annual assessment requirements on mining claims for the year 1907.

As secretary of a Montana mining company, recently successfully financed, and after 16 years residence in the mining regions of the Northwest, I am acquainted with hundreds of mining men and prospectors throughout Washington, Idaho, and Montana, 95% of whom are men of earnest intentions and as honest at least as an average body of men elsewhere. It is a fact that the recent financial flurry has worked temporary inconvenience in every conceivable way to the mining industry and to every individual connected therewith. Among the reasons alleged against the proposed legislation your article states that "the real miner and prospector has done his work by this time, and if not, the financial stringency will not deter him, for his credit is unimpaired." Speaking for thousands of miners and prospectors in the Northwest alone, owning claims, but as yet without capital, and who depend upon their season's savings at other employment (be it with the big mining companies or in the harvest field) to do their annual assessment work in the fall, it is customary to witness the greatest activity in this line of work during the last three months of each year.

This year these useful citizens, from no fault of their own, find their savings temporarily tied up in the banks. Much of their individual credit at the stores is useless, for the reason that the stores in turn have been obliged to retain their wares on the shelves excepting for cash; thus making it doubly difficult or impossible to obtain "powder and grub" and other mining supplies necessary.

The Scripture tells us that "The rain falleth upon the just and upon the unjust." Does it cost us anything either while extending relief in other directions, to render a little timely aid to the mining industry as a whole?

MARK E. DAVIS.

Oakland, November 12.

[We do not agree with the tone of either of the foregoing letters, but we are willing to let others have their say. The writers are, respectively, a lawyer and a promoter; we shall be glad to hear from the prospector himself.—EDITOR.]

The Prospector and His Friends.

The accompanying photographs we owe to the courtesy of Mr. John Daggett, Lieutenant-Governor of Cali-

ornia on his way to Graham Gulch. He did not have a cent, trundling his wheelbarrow for 40 miles from Aetna to Grand Gulch. There he struck a pocket from which he got \$6,000 worth of gold, and thinking that he had ex-

Fig. 1. Ace High.

Fig. 2. A Full Hand.

fornia from 1882 to 1886 and superintendent of the mint in San Francisco from 1892 to 1896. The photographs represent various types of prospectors. The Governor has labeled them with an eye to terms that are used in

hausted it, he sold his claim for \$148 to some half-breed Indians, who have taken out \$30,000 since then. On his return from the diggings, Zalinsky slept in the day time and traveled by night, being in fear of losing his money, which he deposited in a San Francisco bank before returning to work. In 'One Pair' the prospector is better equipped than the wheelbarrow man or the single pros-

Fig. 4. Two Pairs. 'Jacks and.'

a certain well-known game. For instance, the first is called 'Ace High,' and represents a surveyor named O. J. Milton on his way up Black Bear creek in Siskiyou county. It will be noted that he is carrying a complete outfit including a frying pan and blanket, a gold pan, pick, and shovel; other cooking utensils and grab are enclosed within the blanket. The picture labeled 'A Full

Hand' represents a Pole named A. M. Zalinsky, who is a prospector, for he has his faithful burro with him to carry his tools and utensils. In the illustration labeled 'Two Pairs' there appear a couple of prospectors accompanied by two jacks or donkeys. The men are Germans of some experience. They are carrying rifles and the photograph shows how heavily burros can be loaded. In 'Threes' there is a picture of an old prospector named Duulap on his way to New River in the roughest part of Trinity

range. Note the characteristic attitude of the prospector, who is a good specimen of the kind of man that has always lived out of doors. Mr. Dunlap came to California with Gen. John Bidwell, and at the age of 73 he is still exploring in the mountains. His valise is on the front horse and his coffee pot on the other animal. He is evidently well 'fixed.' 'Fours' shows more burros, in

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

It was held negligence in a mining company to permit the taps or nuts on the bolts on the switch in the track to become loose, and the threads on the bolts to become so worn that they would not hold or retain the nuts so as to hold the switch in a secure and reasonably safe condition; and to permit the latch that held the rails of the switch in a proper position to become so loose that it would not remain in proper position, but permitted the points of the rails to become so separated that the motor and cars passing into the mine would split and mount the rails and one car thereby became derailed, and ran against and upon the minor employee whose duty it was to set the switch and to direct the cars on the different tracks entering the mine.

Western Coal Co. v. Burns, (Ark.) 104 Southwestern, 535, July, '07.

It is the duty of the owner or operator of mines to use proper care in placing and setting timbers to support the roof of the mine and to keep them in proper condition. This duty extends also to keeping the roof over the entries and to the roof over the necks of the rooms safe and secure as well as the roof of the mine itself. And for this purpose it is the further duty of such mine owner or operator to provide a competent

mining boss to inspect the walls and roof of the mine and such supports and to see that they are not only properly set but to exercise a continued inspection and that they

Fig. 5. Threes.

this case not heavily loaded but in splendid condition. The photograph is a snap-shot taken as they passed. Taken together these snap-shots of Gov. Daggett illustrate the type of men to whom the West owes so much of its development.

PEAT.—The production of peat-fuel has long been an alluring field. For a variety of reasons most of the numerous disconnected attempts at the utilization of such deposits have largely resulted in practical failure. There seems at present more hope of economically using this embryonic coal in certain districts, but the limitations need to be carefully remembered. The former projects for the production of peat-fuel were to produce a fuel of properties equal and even superior to coal and at a cost slightly more than nominal; these schemes, of course, failed. But the presence of considerable deposits of peat in localities at a sufficient distance from coal-fields seems to offer considerable chance for development by persons able, through training, experience, or study, to cope with the problems involved. There are a very few instances where a fairly good fuel has been produced to sell, with a fair profit to the makers, at roughly \$5 per ton, in localities where anthracite coal brought from \$7 to \$12, and bituminous from \$1 to \$6 per ton, and in localities where hydro-electric power was not available in small amounts at less than \$30 or \$40 per hp. year of 24-hour power. In such few cases the local demand has been stated to tax the capacity of the plants. In all similar situations success may be reasonably expected with proper care in the operation of the peat-plant. The fuel must naturally be made close to the bogs and cannot economically be shipped to a great radius to compete with coal.

Fig. 6. Fours.

are kept sufficiently to render the premises safe.

Brunson v. Southwestern Co., (Ind. Ter.) 104 Southwestern, 593, Sept., '07.

The sale on execution of the mining property owned by the lessor deprived him of all right to royalty under a joint lease made by himself and the owners of other mines where the royalties from all the mines were placed in hotchpot.

Coolbaugh v. Lehigh Coal Co., (Pa.) 67 Atl. 615, May, '07.

History of Cyanidation.—II.

By PHILIP ARGALL.

*It is quite clear that the decisions of the courts have on the whole been unfavorable to the MacArthur-Forrest patents, and by these decisions the claim of the patentees to be considered the sole inventors of the cyanide process is set aside. Furthermore, if we rely on the almost unanimous verdict of the courts we must admit that the cyanide process is a distinctly American invention, and, as I do not know any higher authority, I award the palm of discovery to the inventive genius of Rae and Simpson. No man, however, can deny that MacArthur and Forrest introduced the first cyanide process that commanded universal attention, that they evolved order out of chaos, achieved a brilliant success where others had failed, and finally gave to the world in the process that bears their names one of the most marvelous, though simple, methods of ore treatment that the human mind ever conceived. For this, their names shall be emblazoned high on the banner of metallurgical fame, to be both remembered and honored long after the strife of patent litigation is forgotten and the doctrine of "selective action" shall have passed "as a vision of the night."

The MacArthur-Forrest process then consists of neutralizing the acidity in a given ore with an alkali,²¹ dissolving the precious metals with dilute solution of potassium cyanide,¹⁵ and precipitating the gold on filiform zinc.¹⁶ The modifications of this process are numerous. I shall mention a few to illustrate the more important lines of departure: The patent of J. C. Montgomery of Scotland, July, 1892,²² employing sodium or potassium dioxide as an oxidizing agent in conjunction with caustic soda. The points provided for here were the furnishing of more oxygen and having a strong alkaline solution, as such solutions are more active than plain cyanide and water. The Kendall process²³ of 1892 for quickening the action of cyanide by means of ferro-cyanide of potassium; here it would appear that an attempt is made to hasten the action of the cyanide as well as at the same time conserve its strength; the evolution of nascent cyanogen is probably also introduced for the first time as a feature of the process, imitating, no doubt, the evolution of nascent chlorine in another process, which is well known to greatly augment the dissolution of gold.

Almarin B. Paul appears to have originated wet crushing with cyanide solution in the batteries at the Calumet mill, Shasta county, California.²⁴ In 1891 he asks:

"Why not crush your ore in solution, when you introduce solution after crushing dry? The loss of cyanide by crushing with it is but nominal, and is greatly overcome by the cheapness of working and completeness of cyanide distribution through the pulp in the tanks. This plan is so satisfactory to me that I am done with dry mills for the future."

Wet crushing with cyanide solution in the batteries was a distinct step in advance, but slime-treatment apparatus was not in a sufficiently advanced state to meet the requirements of wet crushing in solution, and so it did not take immediate root in this country. We next hear (in 1896) of wet crushing in solution in New Zealand,²⁵ and later it became the established practice in the Black Hills of South Dakota, from whence it spread over the mining districts of the West. Crushing in the cyanide solution in connection with amalgamation was practiced by me on concentrate obtained from roasted sulpho-

telluride ores in 1897. Crushing in cyanide solution is, I believe, the process of the future, on either raw or roasted ore, and with modern slime-agitation and filtering machinery, leaves little to be desired. In fact, the great advance in fine-crushing appliances during the last few years, coupled with the slime-treatment machinery above referred to, has well nigh rendered the treatment of sand obsolete. It is true that it costs more to grind a given ore to pass a screen of 0.006-in. aperture than to pass 0.02-in. aperture, but the increased extraction usually resulting from the finer comminution of the ore very materially exceeds the cost of grinding, to say nothing of the saving in time and equipment, for at best vats in this cold winter climate are a very expensive installation, particularly when the housing of the vats and the heating of the building is taken into consideration.

The Gaze process²⁶ of 1892, where the use of chloride, bromide, and iodide of cyanogen was introduced as improved gold solvents in connection with potassic cyanide. Gaze found that these halogen salts of cyanogen gave a wonderful stimulus to ordinary cyanide solutions, but he failed to obtain a patent, on account, it is said, of the opposition of the MacArthur-Forrest Co. in New Zealand. Later, Sulman and Teed obtained English and American patents covering the use of bromo-cyanogen²⁷. It cannot, however, be said to have come into general use except, perhaps, in West Australia, where bromo-cyanogen is used in the Diehl process, in the extraction of gold from unroasted or raw sulpho-telluride ores, but even there the cost of that chemical is often fully as much as the cost of roasting and never as effective, so in the end the roasting process is bound to prevail, as predicted by me in 1903.²⁸

Many other oxidizing agents have been patented; indeed I believe I am quite safe in stating that the whole list of oxidizers, or oxygen-furnishing substances, have been covered in one way or another in the patents of would-be inventors, not excepting hydrogen peroxide, which, as is well known, destroys cyanide, and is perhaps the best antidote in cases of cyanide poisoning. Of these various oxidizers but few have been found to have any practical use in the every-day working of the cyanide process.

A substantial improvement in the process of cyaniding was the patent of MacArthur-Ellis in 1896, for the prevention of sulpho-cyanides passing into solution when treating ores containing sulphides soluble in cyanide solutions. This patent provides for the addition of carbonate, acetate, or sulphate of lead, so that the insoluble lead sulphide is formed in advance, and the working solutions freed from alkaline sulphides.²⁹

One of the greatest obstacles to successful cyanidation in the early nineties was the omnipresent slime. My earliest experience indicated that even in dry crushing it was the better practice to separate the dust from the sand and treat each separately, and furthermore the same principle was still more important in wet crushing, where it was usually imperative to separate the slime from the sand. A United States patent was issued to me in 1894 for apparatus to separate slime and dust from ores,³⁰ and was used in the Brodie mill at Cripple Creek and the Metallic works near Florence. My first method for treating the separated fine material was briquetting and roasting, then rough crushing and cyaniding. The high extractions made on the roasted product first turned my attention to the advisability of roasting in bulk the telluride ores of Cripple Creek, at that time almost en-

tirely oxidized, but with the rapid development of the mines they suddenly changed to sulpho-tellurides—in part at least—before we could get roasting furnaces installed in the works.

The decantation process of slime treatment should next be noticed. It was developed in South Africa, and at present practically all the slime on the Rand is treated by this method, which consists in agitating the slime in weak cyanide solution, usually by means of centrifugal pumps, circulating the sludge from one vat to another, then allowing the slime to settle, decanting the clear solution, adding water, and again agitating and repeating the process till the gold in solution is reduced to the tenor of practical requirements. The decantation process has been gradually developed in South Africa by Butters and others; the process now in use was first successfully applied to the Rand ores by Johu R. Williams about the year 1896.³¹

One great advantage of the cyanide process over all other practical methods of gold extraction is the fact that it will dissolve gold and silver from raw or unroasted ores. This feature was naturally made the most of in early day advertisements by the MacArthur-Forrest people. It did not, however, apply on sulpho-telluride ores, in the treatment of which roasting became a leading feature; this was first, I believe, introduced on a commercial scale by myself at the plant of the Metallic Extraction Co., at Cyanide, near Florence, Colorado, in the treatment of Cripple Creek ores in 1896.

Roasting introduced many difficulties and complications, chief of which were the sulphate salts in poorly roasted ores, but these troubles were gradually overcome, and today I can not only look back at the successful cyanidation of over a quarter million tons of roasted ore, but I can also affirm that my experience in cyaniding Cripple Creek ores has led me to the unalterable conclusion that my early efforts were in the proper direction, and that cyanide properly applied is the correct treatment for those ores, because they can be cyanided for about one-half the present cost of chlorinating them and with better extraction. Considerable difficulties were experienced in the early days of cyanidation in securing good precipitation from dilute solutions, until the introduction of the zinc-lead couple by MacArthur,³² and the zinc-mercury couple by Caldecott,³³ made possible the effective precipitation of the gold from the most dilute solutions; meanwhile an electrical process of precipitation by Siemens Halske had been introduced in the Transvaal and worked with considerable efficiency on dilute solutions. The anodes were of sheet iron, the cathodes of lead foil, weighing 0.19 lb. per sq. ft. When precipitating from 84 gr. gold per ton of solution down to 8 gr. per ton, it required 9,000 sq. ft. of cathode surface to precipitate 100 tons of solution per day.³⁴ Improvements in the process, such as the substitution of Andreoli's lead peroxide anodes for the iron plates and the use of a high-density current, did not succeed in bringing it into general use, and though ingenious and somewhat successful, it cannot be said to have spread beyond the control of those interested in the patents.

I will next direct your attention to the Clerici-Pelatan process,³⁵ in which the ore is reduced to extreme fineness (slimed) and then treated by agitation in an electric vat with dilute cyanide solution containing sodium chloride. The tank bottom is covered with mercury or amalgamated plates, to form the cathode of an electrical cell; the revolving stirrers are the anodes; the gold is dis-

solved and precipitated in the mercury. Many advantages were claimed for this process, such as amalgamating coarse gold, dissolving and precipitating the gold in one operation and in one vessel; thus leaching is abolished, as is also the use of zinc.

This process has been tested on a working scale in Colorado and several other Western States, but is, I believe, not in use today to any extent. It proved too expensive, for the sole reason, in my opinion, that the precipitation of the gold from a muddy electrolyte, on such limited cathode surface took too much time; the gold goes into solution quickly enough, but the power spent in agitating the mass during the interval necessary to precipitate the gold from solution is at once the weak and expensive point. To illustrate this: In a test made for me by the patentees in 1894, \$2 per ton in gold remained in solution after 7 hours' operation, while, by passing this solution through a zinc precipitation box, the gold could be reduced to 4c. per ton in 15 minutes. I was, therefore, compelled to report against the process to my principals, and subsequent events have confirmed my conclusions.

The introduction of the cyanide process in West Australia to treat sulpho-telluride ores has been fruitful in invention. These ores contain 15 to 20% lime, and early developed the nasty trick of setting in the vats like so much concrete. (I refer, of course, to the roasted ore.) The first apparent success consisted of amalgamating in pans the finely ground ore, then filter-pressing to get rid of the acid salts resulting from bad roasting; next treating the cakes from the filter-press with cyanide solution, and lastly filter-pressing again to drive out the gold-cyanide solution. This process cost about \$10 per ton, but is much simplified and now reduced to about \$3 per ton.

The process used at Kalgoorlie in its improved form consists of roasting the finely ground ore to break up all sulphates and reach, when possible, a dead roast; next, grinding the roasted ore in pans or tube-mills until 98% of it passes a 200-mesh screen; next, agitating in cyanide solution until the gold is dissolved, and, lastly, filter-pressing direct from the agitators. This method of treatment is known as the all-sliming cyanide process. The fine-grinding methods of ore-treatment developed in West Australia introduced the filter-press and the tube-mill into the cyanide process, both, it is said, by J. W. Sutherland, in 1898, though West claims,³⁶ that a one-ton Johnson filter-press was in use at Hamman's Brown-hill mine in 1896, and about the same time the Lake View Consols Co. was experimenting with a centre-filling filter-press. McNeill³⁷ describes the Hannan's filter-plant as first installed, but the date is not definitely referred to. Knutsen³⁸ claims that filter-presses were first thought of on the Kalgoorlie field in 1897, while Diehl used them (on ores from Kalgoorlie) at Hamburg, Germany, as early as 1896. The tube-mill, flint-mill, or pebble-mill, as it is variously called, has been in successful use in the cement business for some time prior to its introduction in practical cyanide work in West Australia. The tube-mill, as I prefer to call it, has proved to be the best sliming machine so far discovered, but it is nevertheless pushed hard by grinding pans of the Wheeler type even in the sliming of ores, while the pans excel as fine grinders to, say, approximately 100-mesh. The filter-press had a short-lived victory, for by the time it was perfected from an ore-treatment point of view, and the costs reduced to something reasonable, the development of the suction-filters showed clearly that the massive cumbersome filter-press, extremely costly to install and expensive to operate, could not successfully compete with the simpler, cheaper, and much more efficient suction-

filter, which is now rapidly displacing the filter-press in many of the goldfields of the world.

The Diehl process, also used at Kalgoorlie and, in fact, elaborated for the treatment of those particular ores in the raw state, presents some interesting features, if not new departures, in cyaniding. Owing to the high cost of fuel, labor, and power, roasting on this goldfield is very expensive, and while the Diehl process only partially eliminated roasting, yet this method is extremely interesting, showing, as it does, the great possibilities of cyanidation, when the ore is reduced to an extremely fine state of division.

In its latest form the Diehl process is found in operation at Kalgoorlie: First, the raw telluride ore is stamped in dilute cyanide solution in batteries, using the ordinary outside and inside amalgamating plates. Second, the crushed ore is passed over concentrating tables, and the concentrate resulting from this operation is roasted and amalgamated. The third step is grinding the tailing from the tables in tube-mills to an impalpable powder, practically the entire produce passing a sieve of 200 mesh per linear inch. In the fourth operation the slimed ore is agitated in vats for two hours in a 0.2% cyanide solution; bromo-cyanogen is then added at the rate of 0.04% of the dry tonnage of the charge, and agitation continued for 22 hours. The charge is usually complete in 24 hours' treatment, though it may require a further addition of bromo-cyanogen.³⁹ The last operation is passing the pulp through filter-presses, the filtrate going to the zinc-precipitation boxes and the residues in the form of cakes, 39½ in. square and 3 in. thick, to the waste dumps. The cost of bromo-cyanogen in this process runs from 50c. to \$1.50 per ton in ores varying from ½ to 1 oz. gold per ton. The Diehl process is based, first, on the removal of the greater part of the tellurides by concentration and roasting for the liberation of the gold before treating them by amalgamation in cyanide solution; second, sliming the tailing and treating the pulp by agitation in cyanide of potassium solution, to which is added from time to time bromo-cyanogen, which salt will partially attack the tellurides, insoluble in straight cyanide. The success of the process, however, depends chiefly on the thoroughness of the concentration, as high-grade tailing from the concentrating mill invariably means high final tailing after agitation with bromo-cyanogen. The process, in brief, amounts to the removal by concentration of a deleterious material from contact with the cyanide solution, "to be handled by such other methods as the particular circumstances will indicate," as pointed out by me in 1894⁴⁰ in an attempt to show the scope of the cyanide process, and that it could "be applied to ores direct, or as a combination process, with amalgamation or concentration, or both, as may be found most convenient for the economic treatment of the ores." The credit for using bromo-cyanogen on telluride ores belongs to Sulman and Teed.⁴¹ The Diehl process has made no progress outside Australia, and even there it is declining. Where roasting charges are high, the process has a fair chance on ores below a valuation of \$8 to \$12 per ton, depending on local conditions.

Yet another West Australian process is known as the Rickens, an attempted improvement on the Clerici-Pelatan, introduced at the old Telluride mill, Colorado City, about the time of its abandonment at Kalgoorlie, the place of its birth, the improvement consisting of an increase of the active surface of the electrodes by the

addition of side plates in the Rickens vat against bottom plates only in the Clerici-Pelatan, and in circulating the mercury so that in passing over the side plates in streams it kept them soft and active. The precipitation, however, was unsatisfactory, and filter-presses were added to the West Australian plants, so that the auriferous cyanide solutions could be displaced from the residues and the gold extracted from them in zinc-boxes. The process then failed in its most important point, precipitation of the gold. To one who has had experience in electrical precipitation from cyanide solutions and is familiar, not only with the large cathode surface required to obtain complete precipitation, but also the time consumed in effecting it, this result is the only one to be expected. When we stop to consider that the gold in this finely comminuted dust treated in the Rickens vat can be brought into solution in two hours, without the aid of electricity, and separated from the residue by a filter in a similar period of time, and the precious metals precipitated on zinc in 30 minutes, a total for the whole process of only 4½ hours, the uselessness of the process for the treatment of dust and finely pulverized ore becomes apparent. Furthermore, it scores another failure of the oft-repeated scheme so dear to the process inventors, *attempting to precipitate gold from a muddy and foul electrolyte*. Others have since attempted to solve the same problem, but with like result. Hence it has become common knowledge that clear solutions are conditions precedent to successful precipitation from all cyanide solutions; and so we come to the last step in cyanidation in which filtration is the dominant note.

Moore obtained an American patent for a suction-filter in 1903, which was introduced at the Mercur Mines (Utah)⁴² but on account of defective mechanical contrivances the filters were not quite satisfactory and were subsequently abandoned; in other places, however, the Moore filter has been quite successful. The Moore suction-filter, as is well known, consists of a series of leaves, or rectangular cells with permeable walls, through which the solution is forced, when a vacuum is created in the interior of the cell, leaving the solids (slime) to form cakes on the cell-walls. A number of these cells are bound together in a so-called basket and immersed in a vat of slime until cakes of necessary thickness have formed; then the basket is lifted from the vat and transferred to a wash-water vat and the vacuum maintained in the interior of the cell until the soluble gold has been replaced by wash-water, when the basket is again hoisted, brought over the dumping place and compressed air turned on to displace the cakes. A second patent was issued to Moore in 1901 covering some other features in his filtering process.⁴³ The Moore filter might be briefly described as a movable suction-filter in a fixed vat.

Cassell obtained a patent in 1904 for what might be briefly described as a fixed suction-filter in a fixed vat.⁴⁴ In this apparatus the slime and solution are circulated around the fixed filter by means of a centrifugal pump, and when the cakes are finally washed they are displaced by water or air and discharged through the doors provided for the purpose in the bottom of the vats. Both the Moore and the Cassell filters provide vacuum-pipes for lifting the filtered solution from the bottom of the cell to the discharge at the top—usually some six feet—but let us assume the head will be balanced by a pressure of 2.5 lb. per sq. in., and it will be seen that 25% of the vacuum usually obtained in mining districts of the west (10 lb.) is not available for filtration in this form of apparatus. A third type, the gravity suction-filter, will soon be on the market, with capacity for making 25 tons and 50 tons of

filter-cake at each cycle. This apparatus may be described as fixed filters with a movable vat and gravity flow from the bottom of the filter-cells to the vacuum-pump.⁴⁵ When the vat is moved back all the filter-cells are completely exposed and the cakes can be dumped practically dry. Lastly, we have the Ridgway continuous filter, said to be operating quite successfully in West Australia. In this form of suction-filter a central rotating vertical axle carries arms with depending filters which slowly pass through an annular slime-vat while the cake is being formed, thence through wash-water, and next to the dump, where compressed air is turned on to displace the cakes, thus completing the cycle, and the filter again entering the slime-vat for the commencement of the next cycle. The arms are automatically raised when passing from one division of the annular vat to another, and the valves to the strong and weak solution and of the compressed-air line are automatically operated as the machine revolves.

Returning to my brief review of the cyanide process, it is quite clear that no chemical improvement of any moment has been made on the process as evolved by MacArthur and Forrest. Weak solution and filiform zinc are everywhere in use today; ores are universally prepared for cyaniding by neutralizing the acidity with lime, while lead salts are invariably used in the cyaniding of heavy sulphides or badly roasted ores. Improvements have been almost entirely along engineering lines, in crushing or pulverizing, in sliming, in agitating, in filter-press work, and in suction-filters; in fact, all along the line of mechanical engineering improvements have been many, and progress steady and continuous.

A TAILING CONVEYING SYSTEM.—Recently there has been installed at the Mobawk mill on Traverse bay, near Gay, Michigan, a new system for disposing of the mill-tailing. This problem is a very important one in the level country around Lake Superior. This system is designed to do away with the cost and maintainance of a sand-wheel where the natural elevation does not suffice. The idea originated with J. F. Jackson of the Wisconsin Bridge & Iron Works, but it was worked out in detail and built by the Mobawk company. The tailing launders discharge into a large tank a short distance from the mill. The sand settles to the bottom of this tank and is elevated to the desired height by means of four bucket-elevators, the buckets being 21 in. long, 11 in. wide, and 13½ in. deep; these are perforated to allow the water to drain. Each elevator, operated by a 2½-hp. motor, travels at a speed of from 30 to 35 ft. per min., discharging its load of sand into a hopper which distributes it onto a belt-conveyor. This conveyor is an 8-ply rubber belt, 20 in. wide and 700 ft. long, operated at a speed of 300 ft. per min. The water is taken out of the large settling-tank by two launders, each 30 in. wide and 11 in. deep, which discharge into a semi-circular steel launder 52 in. diam. This launder is 740 ft. long, or about 10 ft. longer than the conveyor and is placed directly below it. The sand drops from the end of the belt-conveyor into this launder and is finally discharged at a distance of 750 ft. from the stamp-mill.

MACHINE-SHARPENED BITS seldom last as well as those sharpened by hand, but machine-sharpened drills are ganged and so always follow. This is a great saving, as generally when hand-sharpening is used considerable trouble generally arises from the failure of some of the drills to follow. It seems to the miner that this always happens when he is most pushed for time to finish his round.

Radium in the Rocks of the Simplon.

The principal classes of material which enter into the composition of the massif of the Simplon are: (a) The Jura-Trias sediments, lithologically often much alike and much interfolded; (b) the Paleozoic crystalline schists; and (c) the gneiss of Monte Leone and the Antigorio gneiss, both stated to be of Archean age. These rocks throughout contain radium, and for the most part in quantities much above what hitherto has been ascribed to sedimentary or igneous rocks.

Some 36 typical samples, taken from various points in the tunnel, have been examined. The poorest in radium are certain anhydrite rocks. Certain amphibolite schists go very high. The Antigorio gneiss rises from 10.5×10^{-12} and 8.0×10^{-12} grams radium per gram of rock at the Italian entrance to 23.7×10^{-12} at 4,000 metres inward. Some of the Archean gneisses yielded very high results.

Such quantities of radium if generally distributed throughout the rocks of the massif would be sufficient to disturb any forecast of the temperature which under normal conditions would be encountered at the level of the tunnel. It is suggested that the radium was in fact the source of the discrepancy between the predicted and the observed rock temperatures.

As it is improbable that these results are unique and apply only to this particular sedimentary accumulation and locality, they appear to point to hitherto unsuspected quantities of radium (and its parent elements) in the immediate surface materials of the earth. It seems impossible to avoid the conclusion that these elements were precipitated along with the sediments entering into the composition of the massif. The question then arises whether the accumulation of such quantities of radioactive elements may not enter as a factor in the events attending mountain-building. It can be shown that an area of sedimentation whereon has been accumulated some 10,000 metres of sediments, having a richness in radium comparable with the Simplon rocks, must necessarily become an area of greatly lessened crust-rigidity, and would hence become the probable site of crust-flexure under tangential compressive stress.

Further investigation will be required before such views can be generalized and the importance of radium as a source of instability of the earth's crust be determined.

Apart from any speculations as to the influence of radium as the cause of an energetic substratum, the shifting of radium and its parent elements by denudation must be regarded as a convection of thermal energy, and this convection, if the quantities involved are sufficient, must, under the conditions referred to above and the unceasing action of denudation, become rhythmic in operation, and at the same time must result in shifting the areas of high temperature and crust-weakness from age to age as the site of sedimentary accumulation changes.

THE 'BANKET' OF THE RAND was, according to J. W. Gregory, originally a marine placer, in which gold and black sand (magnetite, with some ilmenite) were laid down in a series of shore deposits. The gold and black sand were concentrated by wave action and collected in the sheltered places between the pebbles; later, after the pebbles had been cemented to form a conglomerate, the black sand was converted to pyrite and the gold was dissolved by the same mineralizing action and re-deposited in situ.

Topographical and Other Notes on the Choix-Guadalupe y Calvo Mining Districts.

Written for the MINING AND SCIENTIFIC PRESS
By A. W. WARWICK.

The Sierra Madre Occidental, of Mexico, is scenically grand; it presents forms as grotesque and as varied in color as the soul of an artist could wish. The magnificent gashes in the ranges known as *barrancas* cause even the

history, however rugged they may be, do not constitute scenery. The fine photographs of the great masses of the Himalayas do not appeal to me like even an amateur's picture of the Matterhorn. The great silent unhistoric Himalayas are just a wall between two countries, and beyond the fact that they are hard to cross, have little interest. The fearful cliffs of the Matterhorn have witnessed heroic effort in which men have lost their lives in an endeavor to conquer nature. But at last they were

Map of a Part of Western Chihuahua, Mexico.
From Surveys by A. W. Warwick.

most unimaginative to pause, wonder, and admire. The range of climate and vegetation, the different racial characteristics of the people, the cliff-dwellers living like the old cave men, the sun-worshippers still practising their rites after centuries of missionary effort, all go to lend these mountains that cloak of mystery which is so attractive to mankind.

It has been my fortune to spend the better part of seven

beaten and were scaled. The Matterhorn has a history that gives an impelling interest to its grand escarpments. Riding the trail with only a mozo, going hour after hour without sight of a human habitation, or bird, or beast, the traveler becomes terribly lonely and weary, greatly adding to the physical fatigues due to riding over those rough unworked paths of the Sierra Madre that are dignified by the name of *caminos reales*. One longs for an

Cross-Section Through the Sierra Madre Occidental.

years in these mountains, mainly between latitudes 25° 30' and 27° and longitude 106° to 108° 30'. I may be permitted to say that ethnology is beyond the scope of my work and that mere pilings up of mountains have long since ceased to be marvels, or even to be appreciated, unless with a sympathetic companion. The country is too raw and lacks that touch of human effort which is required to hold the interest of the average man. Mountains without engineering work of some kind and without

occasional flume or ditch on the mountain, even if it does make a straight line in the landscape. To prevent becoming stale, normal man must have diversion. The first thought is naturally, that a mining engineer could never lack for interests by making geological observations. This is true to a certain degree, and on the first trip over a trail, one has much to see of interest. Mule-back geology, however, has marked restrictions, and mule-back determination of rocks is even more lim-

ited in its scope. Without a map of reasonable accuracy, geological observations have little real value. Without such a map geological relationships are masked or may be entirely misread. No accurate maps of the country in which the writer has been working exist, and an extraordinary ignorance prevails as to bearings and distances of places even very close together. Guides who know the trails to places off the main lines of travel are scarce. Nor is this reproach to be confined to the Mexicans. Of all the engineers who have traveled the trails from Parral to Guadalupe y Calvo, there are few indeed who could give anything like a correct trail-map or locate Guadalupe y Calvo within miles of its true position on the general map of Mexico.

A number of maps of the States of Sinaloa and Chihuahua have been published; they appear to be, in most cases, compilations from sketch maps made by men who were rarely engineers. These sketch maps, of which I have seen a great number, contain no astronomically fixed points, and the distances and bearings seem in most cases to be simply estimates or to have been put on the map from information received from *arrieros* whose knowledge is very much '*mas ó menos*.' For my part, I have an intense dislike to travel in an unknown direction. Not to appreciate one's relative position to known places gives a lost feeling that is peculiarly disagreeable. The trail seems to drag out and to be of no interest. All observations become valueless, for they do not fit into any scheme, nor can they be correlated with facts already noted. One needs a map on which to place data and to read their story correctly.

During the last few years, therefore, a series of maps have been made of the lines of travel, each addition being more accurate and complete. The collection of data and the construction of the map has been the solace of many a weary hour on the trail, and has caused observations to be made that otherwise never would have been thought of. Finally, there can be no question but that the working out of the details of the map has given a knowledge of the country such as the use of a map already constructed by another could never give.

At first the maps made by me were based almost entirely on 'dead reckoning,' that is, on estimated rate and direction of travel controlled by compass readings and the speed of my saddle animal. Gradually, however, considerable detailed survey work was done in a number of districts, and opportunities were presented for determining the correct distances and bearings between a large number of mountain peaks forming convenient base-lines. Laterally, work done in the foothill range has resulted in giving bases, enabling me to close a survey line from the coast to Guadalupe y Calvo. The magnificent mountain near Alamos, known as Los Frailes, rising out of the plains, together with a number of peaks in the foothill range, formed several convenient bases. The great peaks Muinora, Milpillas, and Guilona form three magnificent base-lines in the main Sierra. The latitude and longitude of Guadalupe y Calvo is capable of being determined with slight error, since it has a Federal telegraph office which daily receives signal of mean noon from the national observatory at Tacubaya. Cerro Milpillas can be seen from Guadalupe y Calvo and its distance and bearing closely determined. Thus, by triangulation, the latitudes and longitudes of Guilona, Milpillas, and Muinora are found. These peaks can be seen and identified at long distance and really form the main survey points for the southeastern area. A number of minor peaks, the position of which is accurately known, serve to fix many points. Two of the most important of these are Cerro Estacion; at Las Yedras, and Bufa de Los Angeles, at Los Angeles.

In the northwest portion the base-lines are formed by Cerro Chileno, Los Frailes, Cerro Viejo de Baimena, and Cerro Cocoa; all of these are distinctive peaks capable of being seen from both ends of a three-mile base-line from Cerro Sancillo to the Mina Mexico. From this short base-line many other important places were accurately placed, such as Choix, Lluvia de Oro, etc.

It happens, fortunately, that both the Frailes and Cerro Chileno can be clearly seen from El Fuerte, in which place the determination of latitude and longitude is rendered more accurate by having telegraphic time from Tacubaya. Thus the latitude and longitude of the main peaks, used as the ends of the western base lines, can easily be calculated. This work was all done by ordinary light mining transits, with the limit of accuracy set by such instruments, although every effort was made to check the work and reduce the error to a minimum. Many data were also collected by surveys made in the districts of Los Angeles, Mala Noche, El Tesoro, Sabinito, and Mina Mexico. Upon these bases the map was constructed, taking Guadalupe y Calvo as $106^{\circ} 52' W$ longitude from Greenwich and $26^{\circ} 5' N$ latitude, and El Fuerte as $108^{\circ} 38' W$ longitude and $26^{\circ} 28' N$ latitude.

The positions of most of the points on the map were fixed by intersections of magnetic bearings taken on the peaks, using a mean variation of $10^{\circ} 45' E$. Determinations of true meridian were made generally on Polaris, and gave at

Los Angeles.....	$10^{\circ} 48' E$	Sabinito.....	$10^{\circ} 46' E$
Mala Noche.....	$10^{\circ} 45' E$	Mina Mexico.....	$10^{\circ} 48' E$
Tesoro.....	$10^{\circ} 36' E$	Oran average of	$10^{\circ} 44' 24''$

The instruments used were a light mountain transit, and (for use when traveling rapidly from one place to another), a little instrument with hair sights made by Lallie, of Denver, in which angles could be measured to within one minute, independently of the needle. Of course close 'dead reckoning' was kept continuously on the trail by means of time of travel and a pocket compass with sights. Elevations were determined by the aneroid. Every trail marked on the map has been traveled at least twice, and some of them many times. The result is that every important determination has been checked several times, and a great many absolutely independent determinations have been made for most of the places. Frequently there would be three or four positions for the same place, and when they substantially agreed the average was taken. Many trips over so many trails, together with repeated and careful observations from many hundreds of points, go to confirm the impression that no serious error will be found in the accompanying map, which, however, is merely presented as a reconnaissance map, which may serve as a useful guide to an area of some 5,000 square miles of intensely mineralized country.

The mountain system was worked out from aneroid readings, aided by sketches and observations made from high places. The mountains at first seemed an inextricable jumble, but gradually, as the area covered by travel became more and more extended, the system became clear. In the area studied three distinct ranges developed, the Foothill, the Front, and the main Sierra. On the extreme west the Foothill range rises rather abruptly from a broken irregular plateau of between 1,600 and 2,000 ft. elevation. The summits of this range are flat and mesa-like, reaching a height of 1,300 ft. The east slopes fall easily to a valley through which the Choix river flows northerly, with tributaries of the Sinaloa flowing south. Going east the magnificent Front range rises to heights of 7,500 ft., although the average height is several hundred feet less. The summits are

covered with a fine growth of pine. The great *barrancas* or *quebradas* that cut into this range frequently reach depths of over 5,000 ft. below the rims. This, together with the coolness of the atmosphere and the general sense of being in lofty mountains makes it at times almost impossible not to believe one's self in the high sierras. The petrological character of this range, however, is so markedly different from the main sierra, the general elevations of the crests being at least 2,000 ft. lower, and the existence to the east of a valley often very broad, and with a floor of less than 3,500 ft. average altitude go to establish its identity as a distinct range. It is cut through in the north by the Fuerte river, and at its south end by the Sinaloa river.

On the east side of the valley rise the great west escarpments of the Sierra Tarahumara, deriving its name from the great Indian tribe that long dominated it and which still numbers over 20,000. This range forms, of course, one of the great mass of mountain ranges known collectively as the Sierra Madre. The axes of these ranges run roughly northwest and southeast. A cross-section suggests step-faulting on a gigantic scale. A generalized section from the Pacific coast to the continental divide is presented herewith.

The working out of the drainage system was exceedingly interesting. The watersheds of the Fuerte, Sinaloa, and Culiacan rivers so interlock that the final unraveling was not particularly easy. It was made more difficult by the custom of changing the names of the rivers every few miles, making their identification laborious. The two great river systems of the area are those of the Fuerte and Sinaloa. They present many interesting differences. The Fuerte rises in the high plateau and the tributaries flow in great gashes running northwest or southeast until they meet that great east or west *barranca* known as the Verde, San Carlos, or Guerachic, in different places. These *barrancas* form one of the great natural wonders of northern Mexico and must be seen to be appreciated. The east or west *barranca* is often over 5,000 ft. deep from the rim-rock, with great cliffs many hundreds of feet high rising in succession from the river-bed. The regularity of the northwest and southeast gashes, practically paralleling the axis of the range, suggest that the Tenoriba, Babrugame, Luera, and Chinatu rivers follow fault-planes, nor is it unlikely that the *barranca* of the Fuerte river is also a great east and west fault-plane. It is a curious fact that traveling northeast at right angles to the axis of the Sierra Tarahumara, the tributary river-beds have all approximately the same elevation of 7,000 feet.

A casual glance at the map gives the impression that the Sinaloa river also rose from the high plateau. This is not so. It derives by far the greater volume of its water from the area between the Front range and the Sierra Tarahumara. While readings of from 6,500 to 7,500 ft. are common in crossing strong deep tributaries of the Fuerte, at no point can an aneroid reading of over 4,000 ft. be obtained in a Sinaloa tributary at any point where it could be dignified by the name of river. A few unimportant *arroyos* come off the main sierra to join the Muinora river. The junction of the Santo Domingo, Bazonopa, and Muinora rivers, which form the Sinaloa, occurs at an elevation of only 2,000 ft. A peculiarly majestic scene is that of the Muinora river flowing northwest to meet the Tahomitas, which rushes southeast, both sweeping round the flanks of Cerro Muinora, towering 8,000 ft. above the river-bed. The Sinaloa cannot be said to come out of the Sierra, but flows around its base. The Fuerte river follows definite lines; the Sinaloa seems to wander through a maze of mountain ranges boxing the compass on its way to the sea. The Fuerte flows

through precipitous *barrancas* with walls of volcanic rocks, while the Sinaloa runs through a wider valley with sedimentary rocks prevailing.

Geologically the area is of great interest. The first impression on coming into the country from the east is that it is simply a dreary breccia and tuff-covered mountain district with an occasional small area of andesite, rhyolite, or granite. In going westward, however, the traveler sees a notable variety of rocks, which are of interest not only for their structure, but on account of their mode of occurrence. The southwest portion of the area, to the extent of hundreds of square miles, is covered by sedimentaries. A line drawn roughly between Jecorato, Yedras, and Dolores is the northeast boundary of the sedimentary area. These sedimentaries are of unknown age, owing to the absence of fossils, which were persistently sought without success. Shales and quartzites prevail, but considerable limestone also is to be seen in some portions of the area. As was to be expected, the formation is highly contorted, faulted, or intruded by igneous rocks. In the northwest, limestones are to be found in abundance, and there is strong evidence that they are of Jurassic age.

The geology of these mountains is too complex for off-hand treatment. Practically, the geology has never been systematically studied, and much patient work remains to be done before clear or definite statements can be made even as to the main facts. Economically, the area promises to become one of the most important in northern Mexico, mainly, of course, from a mining point of view. While it contains some fair farming land, good grazing land, and much fine pine timber, these resources are of little value unless the minerals are developed. While, as a general statement, it is true that the mineral area is virgin, yet it contains many notable mining districts either productive now or famous for past production. The most noteworthy districts are those of Lluvia de Oro, Los Cueros, the Choix valley, the placers of the headwaters of the Jecorato river San José de Gracia, Calabacillas, La Cumbre de San Manuel, Jedras, San José de Crucis, Morelos, La Dura, Los Angeles, Santa Cruz de Santa Ana, Refugio, Guadalupe y Calvo. The last three mentioned are known to have produced more than \$60,000,000 during the first half of the nineteenth century when worked by English-Scotch companies. As for districts that have local reputations as good prospects, their name is legion. The country is intensely mineralized and will undoubtedly be heard from, when the right kind of miners take hold of it and transportation is improved.

The country has been well prospected. It is safe to say that after generations of persistent search, all the big rich veins that show well at surface have been found, and in them such ore as can be conveniently broken down has been removed and treated long since. The result is that the country has large numbers of veins with considerable work done on them, and with local reputations as having produced greatly, but with every pound of good ore removed and nothing left to show whether the property is worth re-opening or not. Speaking generally, mines in the sense of having ore reserves developed are few and far between, and these are invariably in the hands of Americans. It is not a country where a man can wander and pick up good mines for a few hundred dollars, as so many seem fatuously to believe. It is essentially a country that needs a happy combination of mining skill and capital behind it to win success.

The largest iron mine is that of the Oliver Iron Mining Co. in Minnesota. It is an open pit covering 200 acres, and will be 160 to 200 ft. deep.

Cyanidation With the Brown Vat.

Written for the MINING AND SCIENTIFIC PRESS
By FRANCISCO NARVAEZ.

The San Francisco mill is situated on a hill adjoining the El Sotol mine; it was designed for pan amalgamation and was transformed into a cyanide plant recently.

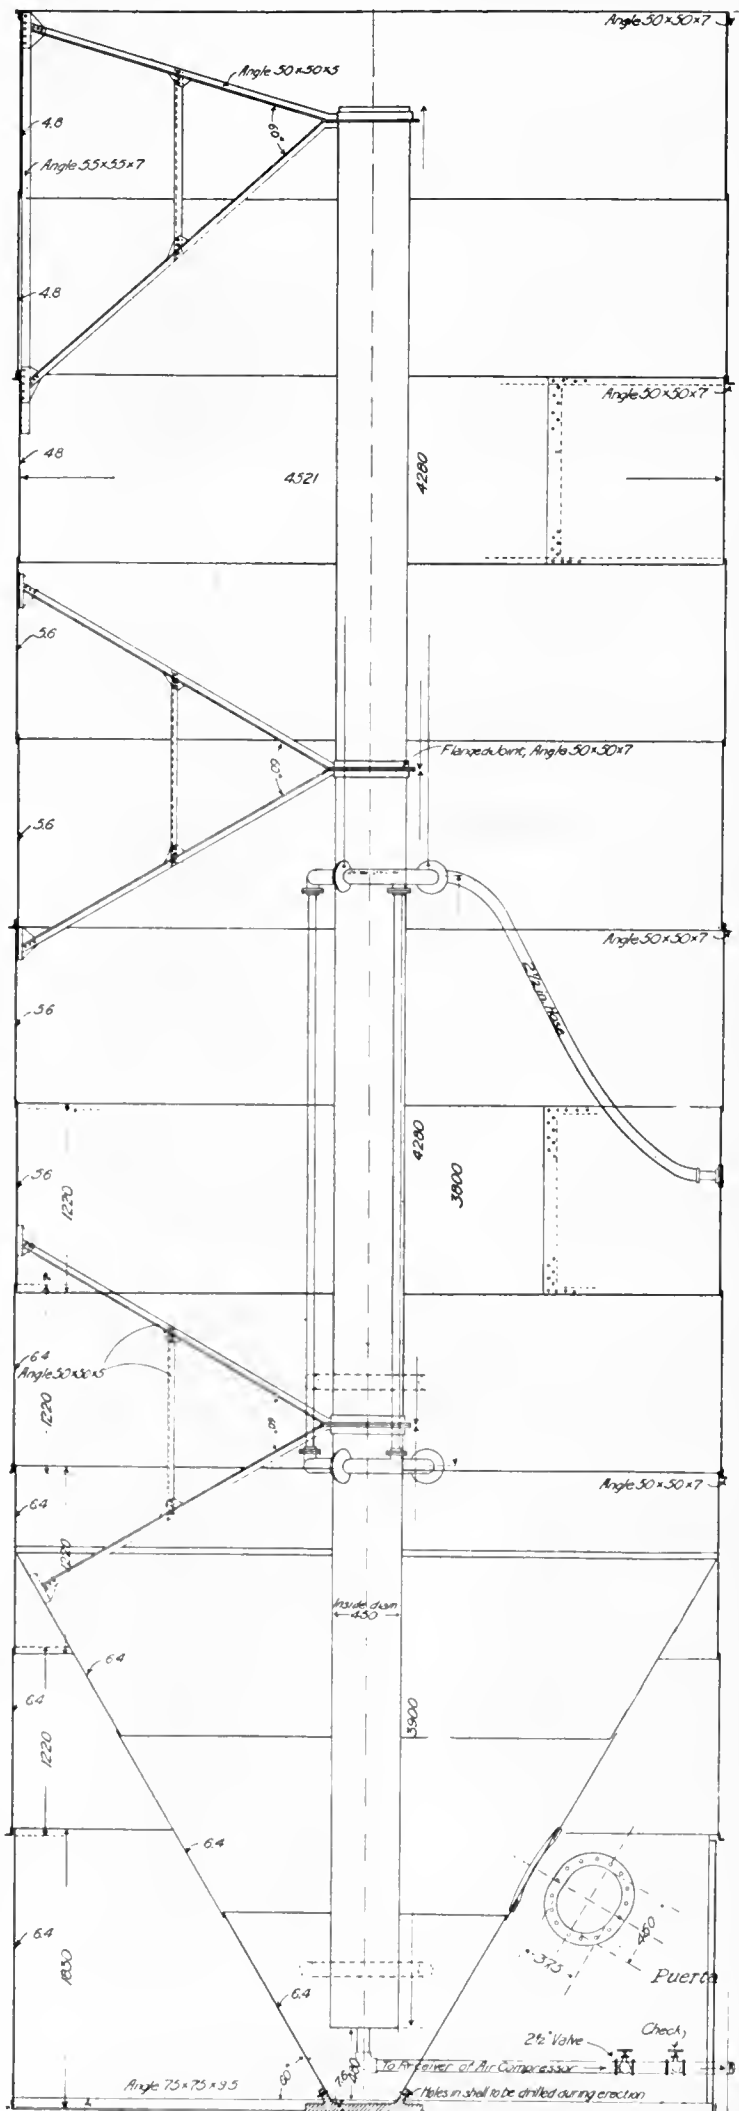

The ore is delivered to the bin of the mill from the Sotol mine by means of a portable track and little cars of 500 to 600 kg. capacity. Before dumping, the cars are weighed on a scale and samples are taken. The ore is broken to pass through a 1½ to 2-in. ring by means of two breakers of the Dodge type, and then it falls to the ore-bins behind the stamps. The mill consists of 30 stamps of 1,050 lb. each, dropping 90 times per minute, through a height of 7 in., using Tyler double-crimped 16-mesh wire-cloth, and grinding at the rate of 2.8 tons per head per 24 hours.

The pulp from each battery is directly discharged, through a 2-in. pipe, onto a Wildfey table, making 250 strokes per minute. This separates about 15% of the gold and silver in a concentrate. The tailing falls into a launder leading to a conical hydraulic classifier. The overflow is sent directly through a 6-in. iron pipe to the Pachuca 'Agitating Tanks,' the underflow being elevated by means of a Frier sand-pump to a battery of Boss pans for re-grinding. These pans have been discarded lately on account of bad results, and are likely to be replaced by two Krupp tube-mills. In the meantime the wire-cloth of the batteries have been reduced (so as to obtain a finer grinding) to 25-mesh of cloth of the same make.

The Pachuca agitating tanks, as they are called locally, were introduced in this district by Albert Grothe, who is the patentee, although the invention is credited to Mr. Brown of West Australia. They are of steel, cylindric in shape and terminating in a conical bottom. The cylindrical part is 30 ft. high and the conical 15 ft., the diameter being also 15 ft., although those ordered for the San Rafael mill will be 20 ft. in diameter. On the inside and in the axis is situated a pipe which runs from top to bottom, 15 in. diam., within the interior of which and in its lower part a 1½-in. pipe ends, which is connected to the receiver of a compressor.

The vats are filled with pulp the consistence of which has varied, but just now it has been found convenient to keep the ratio of water equal to that of ore, the excess water being decanted by overflowing through a 1-in. pipe, which runs on the top of the vats and connects them.

In starting a vat that has been filled, compressed air is applied through a pipe (a) the valve being opened and closed immediately so as to give a blow that disturbs the whole mass of the pulp, which at the beginning of the operation is settled. Each blow of the piston admits a little compressed air, which, in expanding, forces the pulp up and disintegrates it. Repeated blows of air follow, until finally (the whole mass of the pulp having been disturbed) circulation takes place; then the valve of the pipe (a) needs but a little opening for keeping

the mass in agitation, which at first sight looks like boiling water, so effective is the agitation.

The vat is really an air-lift, working under ideal conditions. This system of pumping requires a good submergence. As the mill has not been running continuously, mainly on account of the difficulties with the re-grinding plant, no available data are to hand indicative of the final results to be obtained by this system; but the following are the results of a test which was made on this mill for the San Rafael mine:

Weight of the ore treated, 96 tons of 1,000 kilograms.
Assay in silver, 541 grams.
Assay in gold, 2.22 grams.

SIZING ANALYSIS OF THE PULP.

Mesh.	%
Plus 60.....	0.6
Less 60 plus 80.....	3.4
“ 80 “ 100.....	43.4
“ 100 “ 150.....	1.2
“ 150 “ 200.....	1.6
“ 200.....	49.4
	99.6

Extraction in concentrate: 14.2% silver; 15.4% gold. The concentrate assayed 11.466 kg. silver and 41 gm. gold per ton. Grinding was done with cyanide solution 0.13 to 0.17% KCy, the strength of which was taken up to 0.3% during agitation, 130 grams of acetate of lead being added at that time per ton of pulp. Agitation took place during 48 hours, the proportion of pulp to solution being 1 to 1.47.

The pulp before going to the vats assayed 0.333 gm. silver and 1.6 gm. gold per ton. Samples were taken during agitation every two hours, the residues after 48 hours agitation assaying 60 gm. silver and 0.2 gm. gold; this corresponds to an extraction by concentration and cyaniding of 88.9% of the silver and 91% of the gold.

The filtration of the slime took place in a Butters vacuum-filter, with 28 leaves. The general results have been satisfactory, although for a good running of the plant the filter wants to be at least doubled, because 28 leaves are not sufficient for the capacity of the plant.

A series of tests have been made personally by the writer on a little vat, which permits the treatment of samples weighing 50 kg., the results of which led to the immediate transformation of our present barrel-amalgamation plant into a cyanide mill, an account of which will be given in a later article.

PLATINUM.—The production of platinum in the United States in 1904 was 200 oz., valued at \$4,160; in 1905 the production was 318 oz., valued at \$5,320; in 1906 the platinum production of the country amounted to 1,439 oz., valued at \$45,189, a four-fold increase in quantity, and more than eight-fold increase in value over the figures for 1905. The principal feature of interest in the platinum industry during the year was the phenomenal rise in prices for ingot platinum, which, beginning with \$20.50 per troy ounce on January 6, 1906, had on November 17 reached \$38, remaining at this figure until the end of the year, after which there was another slight rise in price. In February, 1907, for the first time, a distinction was made between ordinary platinum and hard platinum, that is, platinum rich in iridium and osmium, considerable iridium being allowed to remain alloyed in the platinum of the ingots. Such hard platinum was quoted at \$41 per oz. on February 23, and this price held until April 6, 1907, when the placing on the market of more than 100 lb. by a new producer interested in American developments checked the advance, and on May 4, 1907, ordinary platinum was quoted at \$32, and hard platinum at \$35. Then a gradual decline set in, and the price in October, 1907, was \$23 for ordinary and \$25 for hard platinum.

The Jamaica Earthquake.

*The earthquake was accompanied by a loud noise, described as a deep crushing sound, somewhat suggesting distant thunder but with less boom and more of a roar. Intermixed with the natural sounds proceeding from the earth was the crashing of the buildings and the cries of the people, the two together being described as almost deafening. One of the phenomena described by all eye-witnesses was the notable darkness following the shock. The local mortar, rather poor at the best, which was used in most of the buildings, pulverized quickly, and was projected into the air together with other dust in immense quantities as the buildings fell, saturating the atmosphere until it was almost impenetrable to the sun's rays. After the cessation of the shock it slowly settled, covering everything with a thick white mantle of fine calcareous silt.

The greater part of the inhabitants of the island of Jamaica are negroes or mulattoes, although a very considerable number of whites reside in the cities, especially in Kingston and Port Royal. The negroes, although Christianized, retain many of their superstitions and are very demonstrative, a fact which had an important bearing on their behavior and attitude during and subsequent to the earthquake. The very first shock threw them into the greatest fright, but it was far from a paralyzing fright either as regards speech or motion, for the majority fled precipitately from their houses into the streets and open places as a howling mob, alternately screaming and praying, sometimes, it is said, both at once. Even after the vibrations had ceased the excitement and noise continued for some time, and the greatest confusion prevailed. The police and troops were soon out, however, and the wrecked district was carefully patrolled, no one without a pass being permitted to enter. Throughout the shock the whites behaved with a considerable degree of calmness, being without the unreasoning fear which characterized the blacks, yet none could reach the open too soon. Animals, wherever not thrown down by the shock, generally stampeded, horses, mules, and cattle being alike in this respect.

The loss of life on the island, as compiled from identified remains and the list of missing, is officially given as 1,003, almost the whole number of casualties being at Kingston or vicinity. The high death list resulted from the fact that the shock occurred late in the afternoon when the stores and sidewalks were full of people. Outside the city and vicinity the loss of life was not great, although a few people among the mountains were killed by falling rock or landslides. Of the deaths many were instantaneous, but many persons were caught in the ruins and burned in the conflagration which followed the shock.

A SUMMARIZATION of the year's business in imports to this country shows that less than a dozen customs districts are credited with five-sixths of the entire foreign commerce of the United States. Stated in the order of magnitude they are in millions of dollars: New York, 1,480; Galveston, 251; Boston, 230; New Orleans, 217; Philadelphia, 174; Baltimore, 145; San Francisco, 90; Puget Sound, 68; Savannah, 66; Mobile, 28, and Chicago, 25. Considering imports and exports separately, the leading ports are in imports: New York, Boston, Philadelphia, San Francisco, New Orleans, and Baltimore; and in exports, New York, Galveston, New Orleans, Baltimore, Boston, Philadelphia, Savannah, Puget Sound, Detroit, San Francisco, and Buffalo.

* From 'Notes on the Jamaica Earthquake' by Myron L. Fuller in *The Journal of Geology*.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ROUND BUDDLE FOR DRESSING ORES.—No. 869,883; Albert Demuth, Laurenburg-on-the-Lahn, Germany.

A round-buddle for dressing ores having a table consisting of arms slantwise adjustable in a vertical plane, sectorlike plates each attached with one lateral edge to one of said arms and resting with its free lateral edge on the fixed lateral edge of another sectorlike plate, and a flexible cover arranged on the face of said sectorlike plates; and pulp-feeding means arranged above said table.

CONVEYING-MACHINE.—No. 870,050; Percy A. Robins, Englewood, New Jersey.

A conveyor comprising head and tail rollers, a plurality of endless bands arranged substantially parallel to each other, an endless belt supported by said bands and means independent of said rollers for tightening said bands.

METALLURGICAL FURNACE.—No. 869,960; John C. Cromwell, Cleveland, Ohio, assignor to The Garrett-Cromwell Engineering Company, Cleveland, Ohio, a corporation of Ohio.

A furnace having a reciprocating door and a motor for moving the door carried by the furnace, a member adapted to be successively and indefinitely rotated by said motor and a connection between the door and the said member and pivotally secured to the latter.

HYDRAULIC ROCK-DRILL.—No. 869,893; George E. Gjuke, Trelleborg, Sweden.

In a device of this class described, a cylinder, a piston, a fluid pressure chamber on the axial line and to the rear of the cylinder in communication with the rear portion of the

cylinder, and means actuated by the piston for drawing atmospheric air into the fluid pressure chamber upon the working stroke of the piston and compressing it therein upon the rearward or back stroke.

TAPPET.—No. 869,901; Henry Hahn, Stockton, California.

In a device of the class described, a body comprising two members having flat contiguous faces and with oppositely disposed semi-circular cavities in said faces, the flat contiguous faces extending radially of the cavities and in alinement transversely of the cavities, said cavities having internal spaced serrations adapted to engage a rod and said members having transverse slots at opposite sides of the cavities, reversely-arranged wedges received in slots from opposite sides of the body portions, and clamp bolts uniting the body members.

METHOD OF RECOVERING SOLUTIONS.—No. 870,289; Wilbur A. Hendryx, Denver, Colorado.

The method of recovering solutions which consists in introducing a liquid beneath a charge containing a solid and a solution, displacing the solution by the upward flow of such liquid and filtering and thereby withdrawing the displaced solution.

FUSE-HOLDER.—No. 870,531; Robert O. Grooms, Ottumwa, Iowa.

In a fuse-holder, a body-portion adapted to retain a fuse, self-contained means for keeping the holder in position in a drill-hole, and means for guiding the holder to its desired position, said means comprising a ferrule shaped to engage the body portion of the holder and straddle the fuse carried thereby.

The Traylor Concentrating Table.

The table-deck of the Traylor table is divided into two distinct parts; the feed end being absolutely level, both lengthwise, and crosswise, and remaining so at all times; the discharge end of the table is so constructed that it can be raised or lowered, working on an axis, which runs diagonally from a point near the feed-box across the table to the opposite corner. When in operation, the discharge end is raised an inch or two, or just enough to throw the concentrates, which are traveling along the riffles, off to their

in contact with any of the wooden part of the table-deck, thereby preventing warping.

The base upon which the table-deck operates is constructed entirely of steel and is itself braced by several diagonal steel cross-braces, making a rigid construction. The table-deck is supported above this base by a large number of flexible steel uprights which allow of the reciprocating motion of the table. The reason for employing such a large number of these steel upright supports is to make impossible any warping of the table-deck. On the Traylor table the concentrates are fed forward by the reciprocating

motion toward the diagonal axis of adjustment, where they meet the slight inclination of that end or corner, and by this inclination their course is diverted to the launders at the discharge corner. Beginning at the diagonal axis of adjustment, and from there on toward the discharge end, the riffles become lower, until they almost disappear, thereby facilitating the diversion of the concentrates to their respective launders. The heavier concentrate climbs a little higher up on this slightly inclined end of the table, the lighter climbs not quite so far up, the middling still lower, while the sand is washed over the side, all being distinctly separated and falling in their respective launders.

Catalogues Received.

T. H. PROSKE, of Denver, Colorado, has just sent us his instructive catalogue describing the drill sharpeners and heating forges manufactured by him. In this catalogue of only 11 pages there is more information than in many catalogues of much larger size.

The AMERICAN GRONDAL KJELLIN CO., of New York, has just issued Bulletin No. 1, giving much valuable information regarding the magnetic concentration and the briquetting of iron ores. The Grondal Kjellin magnetic separators are much used in Sweden; in this catalogue are many good cuts illustrating their process in use in that country. No binder is used in their system of briquetting.

Publications Received.

'Merek's 1907 Index,' 472 pp., cloth bound, Merek & Co., New York City. This book is issued for distribution to users of chemicals upon receipt of 25 cents. It is a trade publication, which contains much valuable information concerning drugs and chemicals. In it are given the names, synonyms, physical form, and properties of different chemicals, together with their specific gravity, boiling or melting points, etc. It is a handy reference book.

We are in receipt of the following publications of the United States Geological Survey: Bulletin No. 277, 'Mineral Resources of Kenai Peninsula, Alaska,' by Fred H. Moffit and Ralph W. Stone; Bulletin No. 323, 'Experimental Work at the Chemical Laboratory of the United States Fuel-Testing Plant at St. Louis, Mo.,' by N. W. Lord; Bulletin No. 324, 'The San Francisco Earthquake and Fire,' 171 pp.; this is illustrated by many fine half-tones.

respective launders at the far corner of the discharge end and side of the table. On account of the feed end of the table being level, it prevents the water rushing straight across, carrying with it the slime and fine mineral, without allowing time to settle this valuable product. The riffles are in the shape of long regular waves, at an angle of 15°; they are cut into the wooden top of the table and become part of it, instead of being nailed down on the top. This prevents the continual trouble of renewing and repairing riffles. The corners on each of the riffles are filled in, and over all is placed a single piece of hard rubber, giving an absolutely smooth rolling surface without any cracks or shape corners. A smooth rubber surface has a greater tendency to adhere to and hold minerals than is the case on any other smooth surface material. The rubber, covering the entire top of the table, also prevents the water coming

Editorial.

IN OUR ISSUE of November 16 we referred to the proposed abrogation of assessment work on mining claims and we are glad to note that most of the periodicals devoted to mining interests have expressed concurrence with our opinion that such legislative action is unnecessary and likely to prove harmful. The cloven hoof of the spoofer has been detected in this proposal and it is not likely that the bid for cheap notoriety on the part of a certain congressman will prove effective. The real miner is willing to do his assessment work; currency may be scarce, but bacon and beans are plentiful as of old, and no man's credit is as good as that of the prospector.

AT THE PRESENT time 14,500 barrels of cement are being made daily in California and the existing works expect to increase this production to 29,000 barrels per day. Domestic cement is worth \$1.65, and the imported \$3.15, per barrel. The rebuilding of San Francisco and the wider use of reenforced concrete has stimulated the manufacture of cement. The price is likely to become 75 cents to \$1 per barrel for domestic, the quality of which is not as uniformly good as that imported from Germany and England.

ON ANOTHER PAGE we submit a query concerning the cyanide treatment of an ore containing gold both in a coarse and in a fine state of subdivision. It was first presented by a well-known cyanide specialist, who visited San Francisco on his way from South Africa to Mexico. By our request, he prepared the communication to which he now appends the non-committal signature of 'Viator.' We have submitted the problem to several acknowledged leaders in cyanidation and this week we publish the first of the answers. The discussion by Mr. Philip Argall needs no recommendation and we hope that it may lead to a ventilation of practical ideas.

THE LETTER from Mr. A. G. McLaughlin on the subject of 'Wall Street' presents a point of view at variance with the observations made in these columns recently, and for this very reason we are glad to publish his communication. Wall Street needs defenders just at this time and it is fair to say that Mr. McLaughlin makes a good case for the financial centre. In his analysis of the banking situation he is correct, and his explanation of the dominant position of New York as the great security market of America is well stated. As for the rest of the argument, it is that of one who idealises the character of the transactions constituting the larger part of the business of 'the Street.' If brokers themselves did not speculate, if 'wash sales' were a figment of the imagination, if 'puts' and 'calls' were non-existent, if balancing a win against a bankruptcy were

unknown, if bankers did not join hands with brokers, if directors were not speculators in stocks of their own companies, if these and sundry other objectionable practices were no part of the daily fuss and fume of Wall Street, then indeed Mr. McLaughlin's appeal to fair play would make us ashamed of joining populist orators and the great disgruntled in a destructive criticism of the casino on Manhattan island.

IN A FORMER issue mention was made of the absence of rabbits in Western Australia, because the wild-cats of the mining camps had prevented the invasion of a pest so injurious to the other Australian States. Now we learn that during the last few years—since 1900—the rabbits have come in swarms and the Government estimates that 2,000 miles of wire-net fence has been constructed, at a cost of £200,000. So far the fence has proved an effective barrier; the agricultural area has not been invaded, but in the mining districts of the desert the rabbits are to be seen in great numbers; but the miners say that fresh rabbit is better than 'tinned dog,' the vernacular for canned meat. All of which goes to show that the wild-cat has been tamed and no longer serves to defend Western Australia from the South Australian rodents.

IT IS SAID to be the avowed practice of one of the biggest industrial corporations in the country to use any metallurgical method that it may see fit to adopt in the making of iron and steel, leaving it to the patentee to bring suit. If he makes a good case, the corporation purchases the patent; if not, the use of it is continued without further recognition of the patentee's rights. The argument is that a patent must undergo the baptism of litigation before its validity is assured. When the higher courts have given it the stamp of authenticity, it is time enough to pay a royalty or to buy exclusive rights in the invention. This frank piracy is not commended, it is only mentioned as a fact. We are prompted to speak of it by the letter of Mr. Askin M. Nicholas, appearing in our issue of November 9, and by the transcript of his patent specifications, as given on another page of the present issue. He wrote to us from Australia, claiming the originality of a type of filter-press now successfully applied in cyanide mills. Mr. Nicholas was unsuccessful in getting his device introduced, and after spending more money than he could afford, he dropped the business. Now that the idea has been applied, with improvements, by others, all he asks is the recognition due to the inventor of a useful machine. Incidentally, he transmits a bit of advice from the southern side of the equator, warning other inventors to get the service of a thoroughly reliable patent lawyer, if ever they expect to make money from their patents. With the spirit of his communication there is no fault to find and our cyanide specialists will be glad to accord him the honor he deserves. For our part we believe that a patentee strengthens his claim to a royalty when he also can advise as to how the invention is to be applied. The mere devising of a scheme or a machine fulfills only a part of the usefulness of the invention.

Treatment of Silicious Ore.

TALK of starting new smelters at Reno and elsewhere has been provoked by the difficulty in getting prompt settlements from the smelters; but such talk is not to be taken seriously. The 300 tons of high-grade silicious ore available daily from the Goldfield mines would form an inadequate basis for any smelting operation and while the copper ores occurring in the same region might be used in making a suitable mixture, this would not hasten realization on the silicious output, for the matte to be formed would have to be first converted and then refined, and this would be accomplished with no greater celerity by one smelting establishment than by another. Eventually we hope to see the Tonopah and Goldfield districts united by rail to Ely, and then the big plant of the Nevada Consolidated in the Steptoe valley would furnish a market for silicious material, to be mixed with the pyritic ore of Ely. Of course, the wild statements as to an attempt on the part of the Guggenheims or their associates to get control of the gold mines in Nevada by refusing smelter facilities and thereby depressing stock quotations, are hardly worth notice. We hold no brief for them, but it is fairly obvious that they have bitten as much as they can comfortably assimilate and no group is less likely to be buying mines at this time. As a matter of fact, at the back of the talk about a disorganized ore market there is the recognition of a necessity for improving labor conditions, which, at Goldfield, have been out of hand for a long time. Furthermore, the lessees have left some of the mine workings in bad order and a little interval permitting of re-timbering and other repairs will be welcomed by the managers. In the meanwhile the differences between the mine owners and the Western Federation of Miners have reached an acute stage, and we hope that it will be adjusted in such a way as to prevent any further interference on the part of avowed anarchists with the progress of an important industry. Unions we shall have, and they serve a purpose as useful as corporations, but lawless organizations of either labor or capital ought not to be able to persist.

But this problem of treating high-grade silicious ores will solve itself. In every camp the growth of mining and the development of individual mines leads to a lowering of the assay-value of the average output. Cripple Creek and Kalgoorlie, the two great gold-fields of the last decade, were high-grade camps during their early years. Cripple Creek shipped its rich silicious material to the Denver and Pueblo smelters, while at Kalgoorlie the mills extracted the gold at a cost not a bit less than the usual smelter rate. In the course of time some of the high-grade orebodies were exhausted, and the output became less rich, per ton, simply because a general cheapening of operations enabled the managers to exploit orebodies formerly unprofitable, and to mix the poorer stuff with what remained of the bonanzas. As much profit was made on medium-grade ore as was made in the early stages of mining from the high-grade product. At Goldfield the bonanzas yet remain, in large part, but the steady

improvement in methods of mining and milling will gradually eliminate the smelter problem. Cyanidation on the spot will follow in the wake of smelting at a distance. History repeats itself.

The Presidential Message.

THE MESSAGE of the President to the Congress of the United States claims more than the usual attention given to Mr. Roosevelt's utterances and it will be found in accord with the general trend of his policy. We reproduce a part of the message on another page. Discussions concerning interstate commerce and the currency problem constitute the most important features of this document. Again the President essays to define the difference between honest corporations and predatory monopolies, again he undertakes to draw an effective contrast between the energetic useful citizen and the lawless malefactor of the business world, and if, as in most differentiations of the kind, the line between the ethically good and bad is not finally drawn, simply because such demarkations are confused by the factor of motive, nevertheless most of us will recognize the essential truth of his statements and the even more obvious patriotic purpose that prompts the utterance of them. It is his hope so to guide legislation that the country may curb the excesses of an industrial civilization and avoid the dangers imminent upon an unrestrained license in business competition. We see in his attitude as a statesman the expression of an aroused public opinion, aware at last that even national prosperity can prove too costly, if it is to allow a handful of unscrupulous men to control the basic industries of production and transportation. The only regret that, as an entirely non-partisan journal, we feel at this juncture, is that the discussion of methods for bettering business conditions should be hampered by party ties, for the question of the tariff is one that, as an astute politician, Mr. Roosevelt avoids. It ought to be frankly discussed in any fundamental effort to restrict the rapacity of monopolies and the corruption of business.

However, that is dangerous ground for a technical periodical, so we pass on to two other matters. The first of these is the repeal of the tariff on wood pulp; this had already been advocated by Mr. Bryan, himself a publisher, and it seems proper that it should be recommended by another author of exuberant verbosity. It is known to our readers that the wood pulp used in the manufacture of paper has become dear, partly owing to the paper trust, and partly by reason of the depletion of the timber from which such pulp is made. It is desired to remove the duty on this commodity as imported from Canada, and it is hoped that Canada will not retaliate with an export duty. As stated on a previous occasion, we see no need for a special policy in this matter, for the cheapening of print paper is in no way likely to be contributory to the industrial well-being or intellectual development of the country, since it means chiefly that greater facilities will be afforded for the publication of the voluminous drivel of blanket newspapers, devoted

mainly to the narration of things that never happened, to the vulgar description of trivialities, and the weary elaboration of bestialities, to which is annexed a negligible quantity of wishy-washy comment, prepared by underpaid and half-educated scribblers. We want fewer papers and a higher standard; less paper and more ideas; less printing and more honesty of purpose. So let the wood stay in the forests of Canada until such time as it can be used to beneficent purpose. There is enough of it in the United States to serve the needs of the dozen real newspapers that actually guide and illuminate public opinion.

Another interesting subject that finds a place in the President's message is the Bureau of Mines, the creation of which is recommended. This recognizes the demands presented for several years past by the American Mining Congress. It had been hoped by some that a Department of Mines, with its Secretary as a member of the Cabinet, would be created, but if this cannot be done, the mining community will be glad to see the organization of a Bureau of Mines, the chief duties of which will be the collection of statistics, the devising of methods to decrease accidents in mines, the prevention of fraud in connection with company promotions, and the mapping of mining districts. Two of these duties are now performed by the Geological Survey, and it will be a nice question as to how the new bureau will be related to the Survey. Will it be co-ordinated or subordinated? We expect that in the perfectly proper anxiety to preserve the importance and usefulness of the Geological Survey, the friends of that bureau will endeavor to place the new Bureau of Mines under the administration of the Director of the Survey or that the mining organization will be subordinated to the older geological branch. That would be regrettable, if it should further dilute the character of the Survey as a special scientific corps or scatter the energies of its able chief. The mining and the geological branches ought to be co-ordinate, but independent, and they ought to constitute the two parts of a mining department having for its head a man capable of supervising the operations of both. At the present time the Director of the Survey is accountable to the Secretary of the Interior, although as a matter of fact the Secretary of Commerce and Labor is more likely to be in touch with the mining industry. It is proposed to put the Bureau of Mines in the Department of the Interior and this suggests the recognition of geological primogeniture. In any event, we hope that in the effort to make a new departure of uncertain value, nothing will be done calculated to impair the usefulness of an established organization of such unquestioned help to mining development as the Geological Survey. Let us have a Bureau, or a Department of Mines, as may seem best, but let it not further emasculate a technological body, the products of which have done honor to the American application of science to industry. In these matters the President is necessarily guided by specialists and we hope that any considerations of political expediency will not be permitted to over-ride the real necessities of the case.

By the Way.

In his message to the Congress, the President said:

"In any large body of men there are certain to be some who are dishonest, and if the conditions are such that these men prosper or commit their misdeeds with impunity, their example is a very evil thing for the community. Where these men are business men of great sagacity and of temperament both unscrupulous and reckless, and where the conditions are such that they act without supervision or control, and at first without effective check from public opinion, they delude many innocent people into making investments or embarking in kinds of business that are really unsound. When the misdeeds of these successfully dishonest men are discovered, suffering comes, not only upon them, but upon the innocent men whom they have misled. It is a painful awakening whenever it occurs, and naturally when it does occur those who suffer are apt to forget that the longer it was deferred the more painful it would be. In the effort to punish the guilty it is both wise and proper to endeavor so far as possible to minimize the distress of those who have been misled by the guilty. Yet it is not possible to refrain because of such distress from striving to put an end to the misdeeds that are the ultimate causes of the suffering, and as a means to this end, where possible, to punish those responsible for them. There may be honest differences of opinion as to many governmental policies, but surely there can be no such differences as to the need of unflinching perseverance in the war against successful dishonesty.

"In my message of December 5, 1905, I said:

"If the folly of man mars the general well being, then those who are innocent of the folly will have to pay part of the penalty incurred by those who are guilty of the folly. A panic brought on by the speculative folly of part of the business community would hurt the whole business community, but such stoppage of welfare, though it might be severe, would not be lasting. In the long run the one vital factor in the permanent prosperity of the country is the high individual character of the average American worker, the average American citizen, no matter whether his work be mental or manual, whether he be farmer or wage worker, business man or professional man.

"In our industrial and social system the interests of all men are so closely intertwined that in the immense majority of cases a straight dealing man who by his efficiency, by his ingenuity and industry, benefits himself must also benefit others. Normally the man of great productive capacity who becomes rich by guiding the labor of many other men does so by enabling them to produce more than they could produce without his guidance, and both he and they share in the benefit, which comes also to the public at large. The superficial fact that the sharing may be unequal must never blind us to the underlying fact that there is this sharing and that the benefit comes in some degree to each man concerned. Normally the wage worker, the man of small means and the average consumer, as well as the average producer, are all alike helped by making conditions such that the man of exceptional business ability receives an exceptional reward for his ability. Something can be done by legislation to help the general prosperity, but no such help of a permanently beneficial character can be given to the less able and less fortunate save as the results of a policy which shall inure to the advantage of all industrious and efficient people who act decently, and this is only another way of saying that any benefit which comes to the less able and less fortunate must of necessity come even more to the more able and more fortunate. If, therefore, the

less fortunate man is moved by envy of his more fortunate brother to strike at the conditions under which they have both, though unequally, prospered, the result will assuredly be that while damage may come to the one struck at, it will visit with an even heavier load the one who strikes the blow. Taken as a whole, we must all go up or down together.

"Yet, while not merely admitting, but insisting upon this, it is also true that where there is no governmental restraint or supervision, some of the exceptional men use their energies, not in ways that are for the common good, but in ways which tell against this common good. The fortunes amassed through corporate organization are now so large and vest such power in those that wield them as to make it a matter of necessity to give to the sovereign—that is, to the Government, which represents the people as a whole—some effective power of supervision over their corporate use. In order to insure a healthy social and industrial life, every big corporation should be held responsible by and be accountable to some sovereign strong enough to control its conduct. I am in no sense hostile to corporations. This is an age of combination, and any effort to prevent all combination will be not only useless, but in the end vicious, because of the contempt for law which the failure to enforce law inevitably produces. We should, moreover, recognize in cordial and ample fashion the immense good effected by corporate agencies in a country such as ours, and the wealth of intellect, energy, and fidelity devoted to their service, and therefore normally to the service of the public, by their officers and directors. The corporation has come to stay, just as the trade union has come to stay. Each can do and has done great good. Each should be favored so long as it does good. But each should be sharply checked where it acts against law and justice.

"The makers of our national constitution provided especially that the regulation of interstate commerce should come within the sphere of the general Government. The arguments in favor of their taking this stand were even then overwhelming. But they are far stronger today, in view of the enormous development of great business agencies, usually corporate in form. Experience has shown conclusively that it is useless to try to get any adequate regulation and supervision of these great corporations by State action. Such regulation and supervision can only be effectively exercised by a sovereign whose jurisdiction is coextensive with the field of work of the corporations—that is, by the national Government. I believe that this regulation and supervision can be obtained by an enactment of law by the Congress. * * * Our steady aim should be by legislation, cautiously and carefully undertaken, but resolutely persevered in, to assert the sovereignty of the national Government by affirmative action.

"It has been a misfortune that the national laws on this subject have hitherto been of a negative or prohibitive rather than an affirmative kind, and still more that they have in part sought to prohibit what could not be effectively prohibited, and have in part in their prohibitions confounded what should be allowed and what should not be allowed. It is generally useless to try to prohibit all restraint on competition, whether this restraint be reasonable or unreasonable; and where it is not useless it is generally hurtful. * * * The successful prosecution of one device to evade the law immediately develops another device to accomplish the same purpose. What is needed is not sweeping prohibition of every arrangement, good or bad, which may tend to restrict competition, but such adequate supervision and regulation as will prevent any restriction of competition from being to the detriment of the public."

Personal.

H. A. TITCOMB is in Chile.

C. W. PURINGTON is at London.

HENRY KRUMB is at Mohawk, Arizona.

MARK L. REQUA has returned from New York.

T. BRUCE MARRIOTT is on his way to British Columbia.

C. BOETTCHER, of Denver, is in San Francisco for a few days.

T. A. RICKARD spent a few days at Santa Barbara last week.

ARTHUR W. GEIGER is in this City, on a visit from Elko, Nevada.

OSCAR H. HERSHEY is inspecting a mine near Yucca, Arizona.

ALVIN BACON CARPENTER, of Mexico City, is in San Francisco.

DWIGHT FURNESS has resigned as American Consular Agent at Guanajuato.

E. R. ABADIE has returned to Oakland from his mine in Tuolumne county, California.

ARTHUR L. PEARSE sailed on the *Mauretania* on November 30 on his way to London.

J. PARKE CHANNING has returned to New York from a six months' trip in the Northwest.

JOHN C. MCMYNN has resigned his connection with Robert W. Hunt & Co. of Chicago.

C. COLCOCK JONES has returned to Los Angeles from an examination of mines near Congress, Arizona.

A. C. BEATTY, on his return from Mexico and Arizona, met JOHN HAYS HAMMOND at Santa Barbara.

GEORGE WILLIAMS is superintending the construction of the new ore-bins at the Tyee smelter, Ladysmith, B. C.

A. C. REDDING, of Smith, Emery & Co., has returned from a journey in San Bernardino county and northern Mexico.

G. M. GOFYARD of Denver has moved to New York. He will have his office with the Douglas Copper Company, 42 Broadway.

J. J. SMITH, president of the San Xavier Copper Co., Chicago, was recently at Fundicion on his way to his property in the same district.

WALTER J. BROWNING has been appointed general manager of the Rio Tinto Copper mine, in Spain, and leaves for Europe shortly.

JNO. M. BROOKS, JR., Asst. Supt. Compañia Metalurgica y Refinadora del Pacifico, at Fundicion, Sonora, has returned from a vacation in the States.

WILLIAM H. LINNEY, until recently manager of the Nipissing mine at Cobalt, passed through San Francisco this week on his way to Pasadena.

E. A. H. TAYS has resigned the position of general manager for the United Mining Co. of New York and is now in no way connected with that company. He has left Denver for San Blas, in Sinaloa, Mexico.

Obituary.

CHARLES A. MOLSON, one of the best mining engineers in America, died on November 26, at Rea, in Idaho. His death was due to a gun accident while shooting duck and, as no one was present, it is supposed that an accidental discharge of his own gun was the cause of the fatality. He was born at Montreal 45 years ago, and was graduated, with honors, from McGill University. His professional career began in Colorado, where he was employed by the Pueblo Smelting & Refining Co. From Colorado, several years later, he went to Montana, and was with the Granite Mtn. Mining Co. at Phillipsburg. His first important management was that of the Elkhorn mine, also in Montana, where he won a reputation for ability and integrity. This led to his being engaged by the Exploration Company, of London, as

their representative at Salt Lake. For the past ten years he served as an advisory engineer to this important mining corporation, besides doing independent work as a consulting engineer. The sudden death of an engineer so generally liked and respected will come as a sad blow to many members of the profession.

General Mining News.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—On the 12th of November gas was discovered coming from some old stopes on the 800-ft. level of the Gardiner mine of the Copper Queen. The gas had a peculiar alcoholic odor; this gas greatly hampered work, as it affected the miners greatly, in fact rendering a few unconscious in a very short time. Bulkheading was immediately resorted to in order to confine the gas to as small a portion of the mine as possible. On the 15th the gas began to make its way into the workings in the northeast portion of the Irish Mag mine of the Calumet & Arizona Co. The gas became very strong, but after three days it was successfully shut off by bulkheads. It then appeared in the Spray mine and only with great difficulty was shut off there. Up to the present time the cause of it is not known. It is reasonably certain, however, that it is a fire in one of the old stopes of the Copper Queen Co. near the northeast end of the Irish Mag property of the Calumet & Arizona Co. There has been very little stoping done in this ground for over 18 months, it having been practically worked out two years ago. At the present time no effort is being made to put out this fire. It has been shut in on all sides by bulkheads and is not affecting any of the other portions of either the Copper Queen or Calumet & Arizona mines.—A fire started at the Shattuck-Arizona mine Dec. 19. One of the men going to work noticed smoke issuing from the collar of the shaft. He immediately turned in an alarm. The smoke was so thick that it was impossible to go down the shaft or to reach it from the Cuprite mine, which is connected with the 800-ft. level of the Shattuck. After running water down the shaft for several hours, the shaft as well as the drift connecting with the Cuprite mine was bulkheaded and made air-tight. Both these openings were left sealed for several days, after which entrance was made. It was found that the fire had been on the 800-ft. station; the damage is reported as not to exceed \$1,200.—On account of the present stringency in the money market, Bisbee has adopted the Clearing House system. The Copper Queen, the Calumet & Arizona, and the Superior & Pittsburg companies, instead of paying by the usual check, are giving drafts drawn on New York in denominations of \$5, \$20, \$50, and \$100, and \$5 made payable to bearer, and are issuing a local check (not exceeding \$5) for the balance.—The only mines in the district now operating are those belonging to the Copper Queen, Calumet & Arizona, and Superior & Pittsburg companies. The Denn and Shattuck companies were the last to close down, the latter on account of the refusal of the Old Dominion and Copper Queen smelters to handle custom ore. There have been persistent rumors to the effect that there will be a change of management at these two properties.

Bisbee, Dec. 1.

COCHISE COUNTY.

The Lucky Cuss shaft-house burned Nov. 28. The fire was put out before it had extended down the shaft to any extent. The shaft-timbers were charred for a distance of 50 ft., but no damage had been done on the 100-ft. level. The fire is supposed to have started in the change-room, which forms part of the shaft-house. The old hoist, which was used in the palmy days of Tombstone, was completely destroyed.—The meeting of the directors of the Calumet & Arizona Co., which was to be held Nov. 23, was postponed until Nov. 30. During the year this company has purchased mineral land outside the Warren district; these properties have been paid for out of money in the treasury. On at least one of the new properties ore of good quality has been found, and apparently it will develop into a mine.—Several silver and lead properties are being developed near Paradise. The Leadville mine has shipped several carloads of rich lead-silver ore; the Hilltop, the King of Lead, and the Texas have also shipped some lead ore. There are two zones of lead mineralization. One extends from the Leadville mine near Paradise southerly to the Texas mine, a dis-

tance of a mile. This belt is quite wide. The other lead belt begins at the Hilltop and extends in a northerly direction to the King of Lead property.—The annual assessment work on the Scanland property is being done. The east drift from the adit is being extended. The adit is about 450 ft. long. The east drift leaves the adit near the face.

GILA COUNTY.

This week the force employed at the Old Dominion mine will be increased by 75 to 100 men. These miners will be put to work stoping sulphide ore from the lower levels of the mine. For almost the first time in the history of the Old Dominion company no ore is being received from outside camps. This has caused the resumption of mining in the sulphide orebodies, as formerly sulphide ore came largely from Cananea and Bisbee. Considerable concentrate, which was shipped from Cananea before the shut-down, is still on hand, but this will soon be exhausted. The smelter produced approximately 2,700,000 lb. of blister copper during November, of this amount 2,000,000 lb. was reduced from Old Dominion ore. At the mine development work during the week has been quite satisfactory, although a flow of water delayed the work in the cross-cut on the 16th level. A pump has been installed and driving for the sulphide orebody has been resumed.—At the Mallory shaft of the Globe Consolidated, the cross-cut from the bottom of the shaft is now 140 ft. long and is expected to cut within the next 10 ft. the vein prospected on the 460-ft. level. On that level considerable of the ore had been leached, but portions assayed as high as 7% copper. At the Gem shaft they have begun to cut the station at the 1,200-ft. level, but it is not expected that cross-cutting on that level will begin before Jan. 1.—At the Great Eastern shaft of the Superior & Boston Co., the north cross-cut on the 426-ft. level (the same as the Black Hawk 500-ft. level) is now 200 ft. long, but it will have to be driven about 200 ft. farther before it cuts the Black Hawk vein.—The shaft at the Black Hawk property of the Arizona Commercial Co. is now 80 ft. deep.—The directors of the Lake Superior & Arizona Co. have decided not to resume at the property for some time.—The Globe Miners' Union, local No. 60, W. F. of M., has adopted a resolution, asking Mark Smith, the Arizona delegate to Congress, to oppose the proposed suspension of assessment work upon mining claims for the year 1907.—The case of the Old Dominion Co. v. A. S. Bigelow and Leonard Lewisohn has been decided in favor of the company and 20,000 of the 50,000 shares given to the promoters will be returned to the company treasury.

CALIFORNIA.

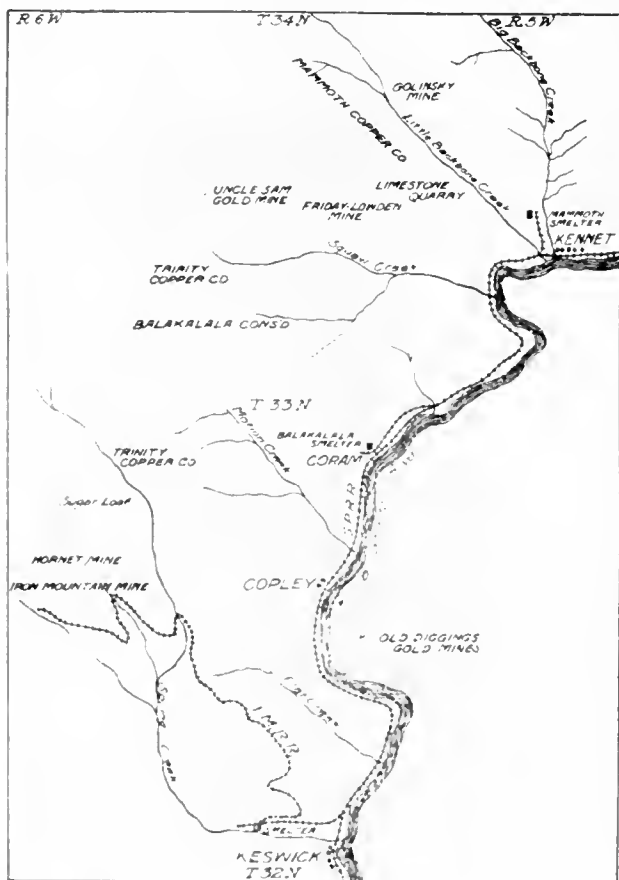

AMADOR COUNTY.

At the Fremont Consolidated mine, near Drytown, a disastrous fire started at noon of the 30th; when the men were lowered at one o'clock the skip stuck at the 1,000-ft. level. Two of the men managed to climb to the surface, but eleven others are still in the mine; four of these men are American, five Italians, and two Austrians. It is thought that the skip was thrown off by the body of one of the miners, rendered unconscious by the smoke. The skip could not be lowered or raised. Great volumes of smoke came from the shaft immediately. Unsuccessful attempts were made to get into the mine from the Gover shaft, which is several hundred feet from the Fremont, and is connected with it on the 700-ft. level. Owing to the smoke it was impossible to effect an entrance that way. On the 2nd, Mr. Goodall, the manager, with several picked miners, penetrated as far as the 600-ft. level, but were overcome with gas, and had to be hoisted again. On the 3rd the fire was under control, but it was impossible to get below the 300-ft. level; it is thought that the shaft has caved at that point.—At the South Eureka mine 40 men are working. Some good ore was recently found on the 2,500-ft. level, but its extent is not known as yet. At the mill for the last six weeks all the stamps have been run only during the day-shift.—Only a few miners are working at the Central Eureka; these are taking out a pillar of rich ore from one of the stopes. A stockholders' meeting of the Central Eureka mine was held a few days ago in San Francisco; this is the

first meeting for 20 years. It seems probable that negotiations will be made with Hettie Green, and that the ground between the South and Central Eureka mines will be prospected.

NEVADA COUNTY.

One of the finest restraining dams in California has just been completed across Greenhorn creek, about a mile above the Narrow Gauge crossing; this is a cribbed dam, 30 ft. wide at the base, 25 ft. high, and 106 ft. long. Work began about three months ago. It will be used to impound the tailing coming from the Nevada hydraulic mine. This mine is mainly owned by J. S. Goodwin of You Bet and the Nichols family of Dutch Flat. The dam will back up the creek for half a mile. The dam has been planned so that it can be built to a height of 75 ft., at which height the creek would flow across a side ridge into another canyon. There is a large amount of good ground in the Nevada property. The pipe-line has been laid to the mine and everything is ready for piping to begin as soon as the winter rains set in.—At the Belle Union mine the adit, which has been driven

Map of the Copper Region of Shasta County, California.

from the open-cut, is now 40 ft. long. This mine is owned mainly by Sacramento and local people.—Wheeler & Gill are driving an adit to the north of the Belle Union to the same vein which was also worked long ago at that point. Both these properties are near Southern's mill and not far from Grass Valley.—The Kenosha mine has been unwatered.—The vein in the bottom of the mine is very promising. Sinking will begin at once; stoping will also commence soon.—George Mainhart of Grass Valley is the new superintendent of the Champion mines. James Moore will stay as foreman of the Champion. Over 100 men are working at the Champion and Home mines; 70 stamps are running at the mill.—A new pay-shoot has been found at the Banner mine. This ore was found on the 900-ft. level. Some time ago, owing to the financial stringency, the miners were laid off; recently Mr. Ball, the superintendent, has been doing some prospecting himself. It was he who blasted into the new orebody. This vein is of good size and is thought to be the continuation of the shoot which paid so well in the upper levels.

PLUMAS COUNTY.

Some rich ore has recently been found at the property of the Antelope Gold M. Co., on Antelope creek, near Clio. On the eight claims of this property there are three veins, the Antelope, the New Ledge, and Hawkeye. The centre vein, the New Ledge, outcrops for a distance of 1,500 ft. In the shaft on the Antelope, the vein, at a depth of 75 ft., is 4 ft. wide, and carries gold, silver, and copper. The Hawkeye vein is 9 ft. wide at the bottom of the shaft, which is 66 ft. deep. The cross-cut adit is now 265 ft. long; it is expected to cut the Antelope vein at a distance of 645 ft. The adit driven to intercept the Hawkeye cut that vein at a distance of 75 ft. from the portal.

SHASTA COUNTY.

At the Mammoth smelter No. 4 furnace will be in operation in about two weeks. The new stack has been completed. A. F. Holden, president of the United States company, the parent corporation controlling the Mammoth Copper Co., states that there is no intention of closing the Mammoth smelter.—The Noble Electric Steel Co., operating at Heroult, has bought the Mount Shasta, the Shotgun, and the Shotgun No. 2 claims on Shotgun creek, also the Carisbrook and the Chrome No. 1 and No. 2 claims; these contain bodies of chrome-iron ore.—At the Gladstone mine, near French Gulch, from 1,800 to 1,900 tons of ore are being treated in the mill each month; the ore is said to assay \$15 per ton. This summer the orebody on the 400-ft. level has been found and now the ore-bins are all kept full—quite a contrast to conditions last spring when the company was hunting for the orebody on the 300-ft. level. About 70 men are working at the mine.—The Milkmaid mine is shipping 2½ tons per day to the Selby smelter. This ore is quite high-grade. About 20 men are working at the mine. The vein is small but the ore is quite rich.—Frank N. Leland, who has just bought the Washington mine, has already started work at the mine.—The electric furnaces at Heroult started up Monday for the production of ferro-silicon, and it is expected that operations will be continued indefinitely. Production at Heroult has been suspended temporarily, owing to the necessity of getting all the power company's transmission lines in order for the winter season, and now that this has been accomplished the high voltage required at Heroult will again be turned on and continued without interruption. The steel cells for the battery of charcoal furnaces to be installed at the electric smelter are in process of construction. In all, fourteen are to be erected. They are to be of the latest design for the extraction of all of the by-products to be obtained from the distillation of wood. The magnitude of the charcoal industry to be created by electric smelting operations on the Pit can be conjectured from the statement that upward of 30,000 cords of wood will be used in a year.—The Keswick plant of the Mountain Copper Co. closed down last week.

SIERRA COUNTY.

The town of Alleghany is greatly excited over the discovery of very rich ore in the old Deep Blue gravel mine at Smith's Flat on the road to the Oriental mine. The ledge is five feet wide; the ore is quartz with gold-bearing arsenopyrite scattered through it and here and there flakes of free gold.

YUBA COUNTY.

At the Mt. Pleasant mine near Camptonville, some rich gravel has been worked during the last few weeks; nuggets weighing from one to five ounces have been found on the bed-rock. The Mt. Pleasant mine adjoins the Orient mine which is owned by North San Juan people. The Orient has just been bonded to an Oakland company; Oscar Jones is in charge of the work at the Orient.—Rich gravel has also been found at the Indian Hill gravel mine which is in the same vicinity.—The adit at the property, near Weed's Point, belonging to C. L. Crane is expected to cut the channel within the next few days.

NEVADA.

ESMERALDA COUNTY.

The output from Goldfield district for the week ending Nov. 28 amounted to 3,570 tons of ore having an estimated

value of \$354,230. The Mohawk Combination lease shipped 2,144 tons; Mohawk, 143; Begole lease, 522; Rogers Goldfield Syndicate, 80; McCoy lease, 18; Florence Annex, 5; total shipments by rail, 2,914 tons. The Nevada Goldfield Reduction Works milled 143 tons of ore from the Mohawk mine; the Combination mill treated 425 tons; the Kinkad mill treated 90 tons.—Practically all of the shipping mines and mills of the district closed down Wednesday morning, owing to the refusal of the miners to take scrip for their wages; the Mohawk Combination, which has been the heaviest producer of the camp the past few weeks, suspended work on Monday, owing to a cave-in which made the workings unsafe; consequently, the production for the week is the lightest for the month. No hope is held out for the immediate opening of the mines, and it is probable that until the financial situation improves and the smelters are able to make prompt settlements for ores, the mines will stay closed. Again the mines of Goldfield are shut-down and not a shaft is working. Again the Miners' Union has invited trouble, by refusing to work on a very flimsy pretext.—At a meeting of the Miners' Union of Goldfield Tuesday night, it was voted that the miners of the district should not work for any company paying its employers in scrip, cashier's checks, or any other than coin or currency; and receiving no assurances from the mine operators that they could or would make any change in the scrip system, adopted by the banks of Goldfield, the miners struck and failed to appear for duty on any of the mines of the district on the following morning. In consequence, there is not a mine in camp at work, and not a lease of consequence. Before taking action, the miners had appointed a committee which met with a committee of the mine owners, and the question was thoroughly discussed from every view-point. The miners were shown that it was entirely impossible for the operators to pay in cash, as the cash was not obtainable. The committee, apparently convinced, reported to the Miners' Union but the report was not adopted and the committee continued, with the hope that some compromise might be effected. But the mine owners' committee had no alternative to offer; the operators were up against a wall, and when the committee from the union sought another interview they were told that it was useless. Thereupon the miners met Tuesday night and voted to strike. Since Tuesday, no effort has been made on either side to come to a settlement, and a dead-lock exists.—The Florence Goldfield M. Co. has declared a dividend of 10c. per share on the issued stock, payable Jan. 2. This will amount to \$105,000.—Owing to the present labor troubles the Goldfield Consolidated has decided to pass the December dividend.

All the trouble among the miners at Goldfield has been caused by about 300 men in that camp. The better class of miners does not attend the meetings of the union, and the state of unrest is maintained by the rabid minority. The people of Goldfield have now determined to have an open camp. Both union and non-union men may secure employment, but the employers have made up their minds that no non-union miner shall be kept from working or driven out of the camp. They are going to act soberly and decidedly before conditions get bad the way they did in Idaho and Colorado. If conditions do not change there will surely be suffering in Nevada this winter. The miners have nothing saved, and those out of work in Goldfield have no other big camps to go to and get work.—There are now about 6,600 mine-workers in Nevada; at Goldfield, nearly 3,000; Tonopah, 1,000; Ely, about 1,000; Yerington, 300; Bullfrog, 200; Manhattan, 200; some at Virginia City, and at the balance of the smaller camps about 500; the wages these men receive range at the different camps from \$3 to \$5, Goldfield being the only \$5 camp. That is more than the ordinary properties can afford to pay operatives. The Comstock in its palmiest days, with living higher than it is now in Goldfield, paid \$4 a day. That is what they pay in Tonopah. Miners in Tonopah say they would rather work there for \$4 than at Goldfield for \$5, because they are surer to be working enough more days to make up for the wages lost at Goldfield due to strikes. Many of the smaller camps are not union. Ely is an open camp. At Goldfield the men continued demanding more and more wages. Now the

owners have called a halt. The business cannot generally afford more than \$4 a day to the mine-workers. Men can live well in Nevada for from \$45 to \$75 a month for board and lodging.

NYE COUNTY.

The shipments from the Tonopah district for the week ending Nov. 28 amounted to 1,690 tons. The Tonopah Co. shipped 1,112 tons; Tonopah Extension, 87; Belmont, 154; Jim Butler, 68; Midway, 211; West End, 57. The Tonopah Co. sent 2,728, the Belmont Co. 1,180, and the Montana Tonopah Co. 1,100 tons to the mills. The total output of the Tonopah mines was 6,698 tons, of an estimated value (the shipping ore being valued at \$70 per ton and the milling ore at \$80 per ton) of \$268,540.—At the Tonopah Extension the north cross-cut on the 1,050-ft. level is progressing rapidly and the formation is improving daily, being the true lode porphyry of the district. Numerous stringers of ore have been cut in this cross-cut recently. The west drift of the 600-ft. level, on which work was recently resumed, is 600 ft. long; at that point the ledge shows a width of 10 ft. and carries good shipping ore. Stoping is progressing with very satisfactory results on the 500, 400, and 275-ft. levels. The usual tonnage of ore is being shipped.—The station on the 320-ft. level of the new shaft at the West End property has been completed. Sinking will begin next week. The usual tonnage of high-grade ore is being mined from the slopes on the 400-ft. level.

BRITISH COLUMBIA.

The following were the ore shipments from the mining districts of British Columbia for the past week: Boundary, 1,273 tons; Rossland, 6,407; east of Columbia river, 3,689; total, 11,369 tons.—The Waverly Hydraulic M. Co. declared a dividend of \$5.50 per share at the annual meeting of the stockholders at Barkerville. This is 50c. per share more than last year. The yardage moved was 27,200, of which 4,600 cu. yd. was from the Lost channel and 12,000 cu. yd. from the Grouse creek channel. The average value was a little less than 36c. per cu. yd. More than half the gold came from the Grouse creek channel, which is therefore richer than the other. While the cleanup was in progress a slide of bedrock amounting to 3,000 cu. yd. or more came down from the west rim of the east channel, covering a part of the uncleared ground, so that not all the gold was recovered this year from the season's piping on that channel. About 144 ft. of the old sluice flume was replaced by new boxes at the end of the season.—The Guggenheims are negotiating for the South Valley group of copper properties on the eastern shore of Howe sound. These claims are situated in South Valley, just over the divide from the famous Britannia group, on which so much money has been expended and which have lately paid good profits when operated on a large scale.—The Federal Mining, Smelting & Refining Co. has bonded the Tangier group, situated on Huxley island, off the east coast of Moresby island, the principal island of the group. The consideration is said to be \$300,000, with a 10% payment in cash on signing the papers; the balance in payments extending over a period of 18 months.—The Copper King group of three claims has been bonded to H. Wulffsohn and E. F. Girling of Vancouver. The properties adjoin the well-known Swede group, which is situated on the east coast of Moresby island, 40 miles from Jedway. The lead is stated to have a width of 125 ft.; much of the ore assays 3% copper and carries \$3 gold per ton. The orebody is quite similar to that on the adjacent Swede group, also recently bonded by the same people.—In spite of the closing down of so many mines and consequent shutting down of several smelters, the Tyee works at Ladysmith continued to keep running. From Prince of Wales island one mine operated by the Alaska Industrial Co. continues to ship ore steadily, and with supplies from the Tyee mine and other producers the smelter is kept in operation. The ore from the mine on Prince of Wales island is high-grade. The Tyee Copper Co. is making important improvements and additions to the smelter. The chief of which are a wharf in Oyster bay, a long incline trestle from the wharf to the smelter, ore-bins on the wharf and about the sam-

pling works, machinery and plant for unloading ore from vessels and hauling it up to the high-level storage-bins, an extension of the power-house, and the installation of another steam boiler and an electric generator.—Frederic Keffer, in charge of the mines of the British Columbia Copper Co., and president of the Canadian Mining Institute, has written the various Western members suggesting that a Western branch be formed. He therefore requests that all Western members attend a meeting to be held at Nelson on Jan. 15, when steps will be taken to organize such a branch. A number of papers prepared for the regular meeting of the Institute will then be read.

BOUNDARY DISTRICT.

There have been no developments of moment in regard to the recent closing of the large copper producing mines and smelters of the Boundary for what is stated to be an indefinite period. The Granby smelter and the B. C. Copper Co.'s smelting furnaces were operated a few days till the valuable flue-dust and bottoms around the works was all cleaned up and turned into blister copper, but about the middle of this week both these plants were blown out entirely. What the next move will be cannot be ascertained from any source; but apparently the mines will not resume until the price of copper advances considerably.—Three men are now employed at the Cariboo-McKinney mine.—Not more than 20 men are now employed at the

EAST KOOTENAY DISTRICT.

The ore shipments from East Kootenay mines for the past week were as follows: St. Eugene, 485 tons; Sullivan, 600; North Star, 234; total, 1,319 tons.

ROSSLAND DISTRICT.

The output of the Rossland district for the week ending November 23 was as follows: Centre Star, 4,120 tons; Le Roi, 3,115; Le Roi No. 2, 665; total, 7,900 tons. This makes a total for the year up to date of 248,114 tons. The Rossland Miners' Union, local No. 21, W. F. of M., voted on November 27 to voluntarily accept a reduction of the wages to those prevailing prior to July 1, when the wages were raised 50c. per day for all underground labor. In the future, machine-men will get \$3.50 and shovelers \$2.75. This voluntary reduction of the wages by the Union itself will result in the running of all the mines in spite of the fall in the price of lead and the other metals which has taken place recently. The vote was carried by a two-thirds majority. The output of the two larger mines has passed the 100,000-ton mark for the year to date, the Centre Star having shipped 118,255 tons and the Le Roi 100,385 tons. The shipments this year will fall considerably under last year's total, and will not nearly reach 300,000 tons. There are numerous causes for this, the most potent of which was the shortage of coke that prevailed during the larger portion of the year. It is certain that, if the supply of coke had been

ample, the Rossland mines would have produced a larger quantity of ore than during any year in their history. It was unfortunate, too, that the shortage should have occurred at a time when the prices of metals were high, and when profits were fairly large. Now that there is plenty of coke the metals have decreased so in price that profits have almost vanished. Nothing special occurred at the several mines of the camp during the past week, and none had any developments to note of special interest. Development continues with good results; the quantity of ore mined was the largest in a number of months.

SLOCAN DISTRICT.

During the past year the heaviest shippers in the Slocan have been: Whitewater, 15,532 tons; Montezuma, 2,900; Standard, 624; Rambler-Cariboo, 323; Canadian group, 85. This was all silver-lead ore.—

Part of British Columbia.

Granby mines, including boilermen, watchmen, office men, etc.—Last week the Sudbury mine, in Deadwood camp, which has been working for some months, discontinued for the winter.—Preparations have been made for continuing work all winter on the Cresus, near Anaconda. In one open-cut ore is shown for a distance of 100 ft.; good ore is also found in the shaft.—Probably nearly 100 men have been laid off in the last 10 days by the C. P. R. and Great Northern on account of the temporary stoppage of mining and smelting operations in this district.—Work is still in progress at the B. C. Copper Co.'s Lone Star and Washington mine, across the boundary line in the State of Washington, being of a development character largely. The ore runs high in copper.

Work has been discontinued on the Sudbury in Deadwood camp. When development ceased the mine was looking well, an 8-ft. lead being exposed at the 150-ft. level. Work will not be resumed until spring.—At the Jewel mine they are driving and raising on the 120 and 330-ft. levels. The orebody is from 2 to 4 ft. wide. On the dump there are from 1,600 to 2,000 tons of ore. Twelve men are working at this property.—After many delays, the electric-driven compressor for the Crescent, furnished by the Allis-Chalmers-Bullock, Ltd., has been installed.

About \$10,000 has been subscribed by local people to help complete the electric zinc plant of the Canadian Zinc Co. at Nelson. Work is now being hurried on this plant. The plan is to treat zinc ore on a basis of electric reduction similar to that successfully employed recently in Sweden. Altogether, some \$60,000 or \$70,000 has been expended already. The plant, as far as shafting and concrete work is concerned, is completed. There now remains merely the installation of machinery and the roofing of the works. The plant should be in operation inside of 90 days and will then begin to treat zinc ore. From lack of this machinery and from one cause and another, the ore has been lying idle upon the dumps, thus preventing in many cases the working of lead properties where silver values are low and zinc percentages are high. As this condition is general all over the Slocan, it will be readily seen that a method which will take care of the zinc will at least double the number of paying properties in this camp as well as many other districts in British Columbia.—Arthur Hendrickson of Lardeau has bonded the Nee-pawa group on Ten-Mile creek. This property is looking extremely well. The Nee-pawa has paid from the surface. The drift adit is now about 800 ft. long; there is high-grade ore developed in several places in the mine.

Special Correspondence.

Johannesburg, Transvaal.

Gloomy Prospects.—Inefficient Kaffir Labor.—Departure of Coolies. Stagnation in Local Market.—The Diamond Monopoly.—Copper and Tin Mining.

A number of annual meetings of gold mining companies have been held in Johannesburg during the past fortnight, and at most of them the forecast (as given by the chairman) for the coming year is distinctly gloomy. The statement made by the chairman of the Glen Deep mine, that since the departure of the Chinese and the substitution of raw Kaffir labor, the profit per month had fallen from £10,000 to £2,000, and the working costs had mounted up five shillings per ton, had a depressing effect on the market and most shares declined. People in London referred to Mr. Schumaker as a pessimist, and hinted that his reference to Chinese labor at the Glen Deep mine was employed to frighten the anti-Chinese party.

But you cannot get away from facts, and the chairman of the Glen Deep simply told the plain truth. His speech accentuates the gloomy outlook for those mines that have been employing Chinese labor. Take the Glen Deep as an example; their thoroughly efficient coolies have been replaced by Kaffirs from Cape Colony, who have signed on for six months. These men have never seen a mine before. It will take nearly three months to teach them how to work. Just when they become efficient, and the Glen Deep profits commence to reach the £10,000 mark again, these black men will leave the mine and the management will start with a new crowd of raw Kaffirs. Under these conditions it is impossible to keep the profits to the high point reached with Chinese labor. The experience of the Glen Deep will be the experience of every mine working with coolies; there will be a serious drop in the profits when they depart.

There are few industries in the world that are called upon to go through such trying ordeals as the mining industry of the Transvaal. Fancy losing a large proportion of your labor every six months or a year! It cost a lot of money, of course, to teach the Chinese how to work in the mines, but when they were once broken in, they remained for three years, whereas the Kaffir seldom remains more than eight months. The fact of the matter is, the general public are just beginning to see what Chinese labor has meant to the Rand these past three years. The leaders of the industry have preached in season and out of season of the utter impossibility of getting down costs by depending entirely on the fluctuating Kaffir labor supply. Now that the coolies are going, and the profits commence to drop, the people will see the force of the argument. Chinese labor on the Rand has proved a distinct success, and if this industry gets into a slough of despond, as seems probable in the next three or four years, it is probable that Asiatic laborers will once more be imported.

No wonder that the sharemarket is almost entirely neglected. Save for transactions in one or two diamond syndicates, hardly any shares are being bought or sold. Money seems to be tight all over the world, and the inducements held out to investors by the Rand, cannot compare with the openings in other parts of the world. A man is not going to put his money into a Transvaal gold mine that will give him his capital back and 5%, when he can get the same terms in a safe industrial concern, like a railroad. The flow of capital to the Rand seems to have entirely ceased, and although desperate efforts are being made to woo capital back by substantial

reductions in working costs, the shocks and disappointments of the past are not easily forgotten.

An interesting announcement was made during the week, namely, that an understanding had been reached by the DeBeers and the Premier, as to the sale of diamonds. Had not these two great producers of diamonds come to some understanding, it is possible that the market for diamonds would have been ruined. For some time past the diamond market has been most unsatisfactory, due to the indiscriminate production of these precious stones, and for the sake of both companies, it is satisfactory to note that the market will be studied in the future, and that diamonds will not become as cheap as marbles. If there is one commodity in the world that justifies a strict monopoly, it is diamonds.

The serious fall in the price of copper has proved disconcerting to many people in the Transvaal who are prospecting for this metal. The copper syndicates will no doubt become fewer until the metal mounts up once more. Very little news is being received from the Gov-

Map of South Africa.

ernment tinfields. Many of the unemployed are anxiously waiting on the Government to redeem their promise and provide work for them on these tin prospects. The work being done by the white men in the municipality of Johannesburg cannot last very much longer, and there is now some talk of the Central South African railroads doing something for these white men when the municipal schemes of the City are completed. By employing the right sort of white men on piece-work, it is claimed that the railroad work can be done as cheaply as with Kaffirs.

Denver, Colorado.

Denver Mint to Coin Silver.—Curtailement of Nevada Shipments.—Causes Contributing to Cripple Creek's Success.—Leasing at Leadville.—Coal Strike.—High-Grading.—Output of Leadville.—Activity at Cripple Creek.

Beginning with December 1 the Denver mint will coin silver exclusively. The whole force at the mint will be put to work coining quarter and half-dollars. The superintendent, Frank M. Downer, says that on coins of these denominations, the capacity of the mint will be about \$80,000. The action of the Government in ordering silver coinage exclusively at Denver is of the greatest importance to the mining industry in Colorado. The bullion buyers have been instructed to increase the amount on hand as rapidly as possible. This increased demand for silver will cause many of the mines that have been closed since 1893 to resume.

Owing to the large shipments of ore from Nevada and

the Cœur d'Alene district, the American Smelting & Refining Co. has had to discriminate in favor of Colorado ore at its Denver plant. More ore is offered than can possibly be treated and in order to protect the Colorado producers, the cost of treating Nevada ore has been raised 10%, which is the second increase within a few days. In addition to this, the payments for these same ores has been deferred from 45 to 60 days, as it takes that length of time to realize on the bullion.

In 1904 E. E. Chase, speaking before the summer session of the Columbia School of Mines at Silver Plume, predicted that Cripple Creek would again experience prosperity through the opening of blind veins. It was his opinion that the most important discoveries in the future would be made by cross-cutting from the old workings. The labor troubles, that made Cripple Creek notorious, brought about just the conditions necessary to cause thorough development. The leasing system as it is being followed out in that camp is proving an unqualified success and a great deal of the present prosperity and increased output from these rich mines is due to the astuteness of the miners in finding ore when it is to their own advantage to do so.

At Leadville the recent fall in the price of silver caused some of the lessees to suspend operations, both on the dumps and underground. The demand for silver at the Denver mint will doubtless change this condition. Since the appearance of the brochure recently issued by the United States Geological Survey, giving the results of Emmons' and Irving's work, a great deal of interest has been manifested in diamond-drill work in this camp. The Western Mining Co. is now doing diamond-drill work on its property that will test the conclusions arrived at by the geologists and prove whether the producing area will be greatly extended.

The local strike at Colorado Springs, which has been conducted in such an orderly manner, is slowly gaining ground. The Keystone coal mine has been sold to the Tudor company and is now being operated. This is one of the oldest wagon mines in the district and has been idle since the beginning of the strike. The new management has signed an agreement with the officers of the union, in which all the demands of the miners have been acceded to. This makes all the wagon mines under union conditions, and it is a credit to the union to secure this much of its demand in so peaceful a manner.

The curtailment in output from the Leadville mines and the consequent reduction in the number of men employed is quite evident as the figures for the monthly tonnage begin to appear. Some of the mines are doing development work, while others are stocking ore, preferring to hold it until more favorable prices and conditions are offered by the smelters. The smelters should not be criticized too severely, however. It is their business to extract the metal from the ore. If there be no demand for their product they must necessarily reduce their output.—Transportation facilities are still inadequate to handle the large tonnage from the Cripple Creek district. The Florence & Cripple Creek (narrow-gauge) road has every car and locomotive that it owns, can lease, or borrow, pressed into service. The broad-gauge roads are unable to get sufficient cars to supply the demands made upon them. It is conservative to say that at least 5,000 tons more would have been produced had it been possible to get it to the mills. As it is, the plants at Colorado City and Florence are receiving about all the ore they can handle. About the only remedy is to erect cyanide plants at the mines to treat the low-grade ore, as is being done at Stratton's Independence and a few other mines. The difficulty of treating the unoxidized ores is, however, a great drawback. Under present conditions it might be

wise to give the bromo-cyanide process for telluride ores another trial.

Salt Lake, Utah.

A Lawsuit.—Utah Copper Co.—Bullion Settlements.—Newhouse Corporation.—Ohio Copper Finances.—Tintic Mine Owners.—Coinage of Silver.

The Colorado Mining Co., operating in the Tintic mining district, has been made defendant in a suit filed in the District Court of Utah; Joseph Wilson, one of the original incorporators, has sued to recover 233,336 shares of stock, which has a market valuation of about \$2.50 per share at the present time. The directors of the company refuse to recognize Wilson's claim as being a valid one, and state that they have evidence to show that the plaintiff disposed of all his interests seven years ago. The Utah Copper Co. produced a little more than 3,000,000 lb. copper during the month of November, according to a statement made by the management. The mill is operating satisfactorily with seven units in use; the eighth is to be started during the present month. The ore and bullion settlements reported from Utah companies for November amounted to \$1,929,000, as compared to \$3,012,000 during October. Settlements for the last week of the month aggregated \$346,000.

Orders have been received at the local offices of the Newhouse Co. to resume operations as before the recent curtailment. During the past few months this company has been operating its mill only one shift per day, and had entirely suspended shipments of crude ore. The Boston Consolidated, under the same management, but operating at Bingham, is also displaying more activity. One steam-shovel is working on the porphyry ore, which is being delivered to the bins of the new mill at Garfield. The smelter of the Yampa Smelting Co., at Bingham, is again in operation; the plant is running close to its capacity of 750 tons per day. The new tramway will be ready this week; then the company will no longer have to depend on the Rio Grande & Western railroad. Thomas Weir, who has returned from the annual meeting of the Ohio Copper Co., of which company he is a director, states that the mill, now under construction at Bingham, will be ready about March 1. He states further that the company has been financed, and that there is little reason to doubt that the plans outlined several months ago will be carried into execution.

At the annual meeting of the Tintic Mine Owners' Association, Clarence E. Allen was elected president; John Bern, vice-president; H. S. Joseph, treasurer; and George W. Riter, secretary. The association was formed two years ago, originally for concerted action when the producers were trying to obtain better smelting and freight rates on ore. When the association became well established, the scope of its usefulness was enlarged until now all matters pertaining to the welfare of the mine owners of the Tintic district are referred to the respective committees of this organization.

The question of the Government coining 50,000,000 oz. of silver as a means of relieving the present financial stringency is meeting with popular favor in Salt Lake, and the Commercial Club has taken steps toward calling a convention, at which several of the Western States will be invited to send representatives. Solomon Guggenheim suggested this means of increasing the currency of the country while in the city recently. The object of the proposed convention is to get the matter before Congress in the proper manner. The advocates of the movement insist that there is no intention of bringing politics into the issue by advocating free-coinage of silver, but

that it is purely an emergency proposition and nothing more. Neither the date nor place for the holding of the proposed meeting had been fixed at this writing, but probably will be within the next few days.

The Salt Lake smelting concerns (the Bingham Con. and United States), that signified their intention of leaving Utah, have their plants still in operation. The former is cleaning up the ore in its yards, while the latter is running at full blast, but is not accepting the tonnage which it did before the closing order was given. With the exception of the Mammoth mine, the receipts of ore from the Tintic district have been greatly diminished.

Pioche, Nevada.

Trains Running to Pioche.—Treatment Schedule.—General Conditions in the District.—Wages.—Nevada Utah Co.—Assessment Work.

The railroad is here, unballasted and still in the hands of the construction department, but a mixed train comes and goes every day approximately on time. Mails and express still come by wagon, but these also are to come by train in a few days.

The following schedule has been established for ore: It is based upon net smelter returns, which means gross assay value, less smelter and assay charges. The rates apply from Pioche to Atwoods, Bingham Junction, Garfield, Germania, Hanauer, Murray, Pallas, Salt Lake City, Sandy, and Springville, Utah, and are for \$20 ore, \$4 per ton of 2,000 lb.; \$30 ore, \$4.50; \$40 ore, \$5.25; \$50 ore, \$6; \$60 ore, \$6.50; \$70 ore, \$6.75; \$80 ore, \$7; \$90 ore, \$7.25; \$100 ore, \$7.50; \$150 ore, \$9; \$200 ore, \$10; \$250 ore, \$11; \$300 ore, \$12. From \$300 up to \$1,000 per ton the rate is made by adding to the rate for \$300 ore 2% of the excess value above \$300. A minimum carload is fixed at 40,000 lb. On lots of one to four tons the rate is 40% in excess of the carload rate. Between four and twenty tons the rate is 20% in excess of the carload rate. The average length of haul which these rates cover is about 375 miles, the elevation to be surmounted aggregates about 3,250 ft., and as \$20 ore (net) will constitute probably the bulk of the shipments from the camp, a rate of eleven mills per ton per mile is extremely reasonable.

D. W. Brunton and T. R. Woodbridge for the Taylor & Brunton Co., R. S. Rainsford for the American Smelting & Refining Co., and F. A. Earls for the United States Smelting, Refining & Mining Co., have each recently spent several days looking over the possibilities of the camp for ore supply. This seemed to be rather for the purpose of acquiring knowledge for future use than for present application, as all of them were very positive in stating that there is at present no open market for ore. The United States Co. is refusing to buy ore, and has announced its intention of closing its plant at Bingham Junction in obedience to the recent decree of the United States Court. The Utah Consolidated and Bingham Consolidated have each closed its plant, so that now there is actually no competition in the ore market. Owing to the declining prices for silver, lead, and copper the American Smelting & Refining Co. has been compelled to raise its smelting charges, and accepts no silicious ores except those under contract.

All the above conditions, added to the monetary stringency, have produced their inevitable result here. The Nevada Utah has closed down its mines on the hill and put the machinery into condition for a shut-down of indefinite length. The Mendha, Bristol Consolidated, Ida May, and Comet properties are idle. The Ohio Kentucky, Boston, Lincoln Nevada Prince Consolidated, Nevada Horn Silver, Ohio Pioche, and a number of smaller properties are all working. As an offset to the

closing of the mines on the hill, the Nevada Utah has largely increased its force at Jack Rabbit and has begun shipping the excellent fluxing ores from the Day mine there. It is its purpose to ship 200 tons per day if, as C. H. Swanton, the superintendent, says, it does not involve too much loss; that ore averages quite low-grade at best, and the recent decline in silver and lead threatens to take away the margin of profit.

Since the closing of the mines on the hill there has been much talk about the wage scale. It has been rumored that the Nevada Utah proposed to continue work if the men would accept a lower scale. This rumor I have been unable to verify, but it is certain that there was some foundation for it. The local branch of the Miners' Union took the matter under consideration and promulgated the following as the conditions governing the employment of labor in this camp: An eight-hour day, patronizing company boarding houses not compulsory, miners driving, cross-cutting, or stoping \$3.50, shaft work \$4, muckers \$3.25, cage or skip tenders \$3.50, timbermen in mine \$4, timber framers \$4.50, pipe-men and track-men \$3.50, blacksmiths and tool-sharpeners \$4, engineers \$4, surface men \$3, machine-men, both runners

Map of Eastern Nevada.

and helpers \$4 if company furnishes gum clothes, and \$4.25 if the men furnish them. As this scale is somewhat higher than the scale which the Nevada Utah has been paying, it does not suggest any immediate expansion of activity.

The Boston & Pioche has been sinking a new working shaft which has recently holed into the high-grade ore-body in the Yuba East. It was their intention to begin shipping as soon as this was accomplished, but under present conditions in the ore market they will have to wait for a time.

There is an almost universal opposition here to the proposition that Congress abate the requirement for annual expenditure on mining claims. The argument is that such a law would benefit almost exclusively wild-cat companies, who have withdrawn from exploration and location a vast amount of the mineral-bearing public domain, and that such a law would work great injustice to *bona fide* prospectors.

The crisis through which we are passing will doubtless bring prolonged distress to this mining district. Recovery may be slow. Many readjustments must be made before mining for silver, lead, and copper will again be profitable, but the conviction among all well posted mining men is that the outcome for this county will be beneficial.

Butte, Montana.

November Output.—The Cooke District.—Tungsten Ore in the Butte Continental District.—Southern Cross Mill.—Ore in Calumet Mine of Butte & Bacorn Co.—Progress at Butte & Arizona Properly.—Developments in Vicinity of North Butte Properties.

The copper production of the Butte district in November was 8,679,750 lb., while the normal production is from 28,000,000 to 32,000,000 lb. There was a slight increase over the October output, notwithstanding the almost complete suspension of the Butte Coalition Co., which has been taking out only about 50 tons per day in the course of development work. Otherwise conditions have not changed much during the past two months, and there is no prospect of an early increase in operations. The total production remains about a fourth of the normal, but the working forces at the mines is much higher, probably about 40 % of the normal, a fact that has necessarily increased the cost of production considerably. The grade of ore being mined under the restricted output

a smelter. A small smelter has been running intermittently at Cooke, but the great handicap has been the lack of transportation facilities. The reports made to the backers of the new company are so big that they might be regarded as too good. Veins 50 ft. wide, assaying 5 % copper as an average and carrying some gold and silver, have been opened and are being worked. The prospects of this new company are situated about 15 miles northeast of Cooke, in a separate mountain range. The deposit is in a basin, containing about 400 acres, on top of Goose Lake Mtn. The basin is 10,000 ft. above sea-level, and has two lakes in it, connected by a small stream; the copper deposits are near the lower lake. The men, who discovered this orebody, have partially developed it by two open-cuts at the bottom of the basin. One cut is 50 ft. wide and 6 ft. deep, and the other is 25 ft. long. The entire bottoms of the cuts are in sulphide ore assaying 12 % and better, carrying also gold and silver and, it is reported, platinum.

Several fine deposits of tungsten have been discovered in the Butte Continental district, east of the city; high-grade tungsten ore is being mined from the Birdie claim by Fred Tomek and associates. The Birdie is owned by Samuel Beers and others, and is situated just east of the State of Maine and Mountain Lion claims, properties upon which considerable development work has been done, and is three claims west of the property of the Butte Continental Mining Co. There is an adit 1,800 ft. long on the Birdie in which several stringers of tungsten were cut. Samples of this ore were sent to Denver and the assays returned were high. Tomek and Beers sank on the stringers and opened a body of ore six feet wide; they then drove on this ore for 30 ft., the vein growing larger as the drift progressed. Thirty tons of the ore were concentrated, three into one; and the concentrate assayed 60 % tungsten. Tomek says he has a contract with Pittsburg people to take all their concentrate at \$1.50 per lb., the contract requiring the concentrate to assay 60 % tungsten. Tomek, who is an experienced miner and engineer, says that there is a deposit of tungsten on the Louisiana claim of the Butte Continental Co. Preparations are being made to develop the Birdie extensively.

The waning interest in copper has induced many mining men to return to their first love, gold mining. Lee Mantle, A. E. Springs, and H. L. Frank have resumed operations on the Southern Cross mine, west of Anaconda. A new mill has been erected and has been successfully operated on test runs. The ore of the Southern Cross is not high-grade, and is strictly of a cyaniding character, although the ore carries some coarse gold that can be saved by amalgamation. The mill has a capacity of 100 tons per day and was erected at a cost of \$100,000. The ore is first run through crushers and then through rolls. The ore is fed automatically into a Chilean mill; from there it is sent to the amalgamation plates, where the free gold is recovered. From the plates the tailing is conducted to a Dorr separator, where the sand is separated from the slime. The sand goes to the cyaniding plant, where the usual process is used. The slime is treated in a Moore filter. It is believed the mill will prove a success.

At the Calumet mine, belonging to the Butte & Bacorn Co., during the past week streaks of good ore have been found in the drifts on the 1,000-ft. level. The company is driving east and west on two large veins, but nothing of importance was discovered in the east and west veins. During the past week the drifts intersected some northwest and southeast veins forming a juncture with the east and west vein, and these carry ore. It is the history of Butte mines that the northwest and southeast veins

Montana.

is also very much higher than that mined when the price of copper was higher.

The total ore tonnage and copper production, credited to the various companies for November, were:

Companies.	Tons of ore.	Pounds of copper.
Boston & Montana.....	30,000	2,400,000
Anaconda.....	33,750	2,531,250
Butte & Boston.....	1,500	292,500
Washoe.....	3,000	216,000
Parrot.....	1,500	270,000
Trenton.....	3,750	243,750
North Butte.....	11,250	1,125,000
Butte Coalition.....	1,500	120,000
Original.....	15,000	1,200,000
Miscellaneous.....	3,750	281,250
Total.....	111,000	8,679,750

Butte and St. Paul men have for some time been engaged in examining properties in the Cooke mining district of Montana, just north of the Yellowstone National park, and their reports are favorable. W. W. McDowell, W. E. Reynolds, and Guy W. Stapleton of Butte, associated with some St. Paul capitalists, have acquired a number of the best copper claims and have organized the Goose Lake Copper Co., capitalized for \$5,000,000. The stock is closely held and none is offered for sale, the working capital being subscribed by the Butte and St. Paul men. Desultory mining has been carried on in the Cooke district for years, but the mines are far from a railroad and the old miners and prospectors have not had the means to build a road. The new Goose Lake Co. plans to build an electric road from Cooke to Columbus on the Northern Pacific, and to erect

are the richest at depth, but are not rich near the surface. The North Butte veins are of that character.

Reports from the mine of the Butte & Arizona Co. in Arizona continue optimistic. Caspar Schultz, the superintendent, reports to the officials in Butte that the long adit, which is being driven into the mountain to get under the big copper croppings on the surface, should reach the orebody within 30 days. It is now about 1,900 ft. long and will cut at a depth of 800 ft. the vein which outcrops at the surface. The Butte & Arizona is well financed and has been economically managed. Some good ore has been encountered in driving the adit, but little exploration was done on it, as the big vein was the objective.

The Pilot-Butte Co. is making good progress in the shaft being sunk by it near the North Butte properties. In October the shaft was sunk about 100 ft., and that record was about equaled in November; the shaft is now 320 ft. deep. When a depth of 500 ft. is reached, cross-cutting will begin. W. A. Clark has opened a good copper vein at a depth of 500 ft. in the Elm Orlu, an adjoining property, and that has encouraged the management of the Pilot-Butte in the belief that similarly rich ore will be found at 500 ft. in the Pilot, which is surrounded by producing mines. The Elm Orlu is taking out high-grade silver ore to the north; to the East the Butte & Superior is operating, while to the southeast the North Butte is working; to the southwest is the Badger State of the Boston & Montana. Since the Pilot-Butte began operations, the Carlisle and Protection claims, adjoining the Pilot on the east, have been purchased by Eastern men for \$400,000.

Cripple Creek, Colorado.

District Flourishing.—Gold Payroll.—Gold Dollar Co.'s Report.—Drainage Adit.—Independence Mill.—Gold Sovereign Dissention.

While the financial situation has had a tendency to paralyze many classes of industry, it has had a rather stimulating influence upon the Cripple Creek district, through the demand for gold currency; a great revival is experienced in trade conditions as well as in mineral output, due no doubt to the fact that all payrolls have been met in gold by the banks. The Union plant at Florence, which recently resumed operations, is handling about 20 cars per day. The rolling stock of the Florence & Cripple Creek railroad is being taxed to its full capacity to care for the tonnage shipped over it; the shortage in broad-gauge cars is still felt. The decision of the United States R. & R. Co. to raise the charge on outside custom ores 10% and the deferring of settlements from 45 to 60 days does not apply to Colorado, but is made in order to curtail heavy shipments from Canada and Nevada.

It is reported that the Blue Bird mine, one of the most favorably situated mines on Bull hill, is to resume January 1; bad air was the original cause of shutting down; this condition has been overcome and development work will soon begin. The American Leasing Co., which was recently organized, has secured a two-year lease on the Commonwealth property in Arequa gulch. The officers are Henry G. Stoddard, president; George C. Stoddard, secretary; B. L. Hoffmeister, vice-president; Henry K. Thomas, treasurer, and Louis F. Price, superintendent. The main shaft on block 8 of the Cameron school section, which is now 725 ft. deep, is to be sunk to a depth of 800 ft. This is one of the best low-grade leases in the camp; several thousand tons of ore are blocked out and shipments will commence on resumption of treatment by the Golden Cycle plant at Colorado City.—A depth of 325 ft. has been attained by Lambright & Co. in the main shaft of their Raven & Beacon hill property; this is being

sunk to reach the Ophir dike; a cross-cut will be run north from the 400-ft. level if the vein is not encountered before then. The Ophir is a steady producer.—The Delmonico property has resumed after a shut-down of two weeks for repairs to machinery.

The famous W. P. H. lessees, Harrison & Seaver, have returned to the camp and will try their luck on Galena hill; they have secured a lease on the Lucky Two Fraction, east of the Hoosier and Bob Lee properties on Tenderfoot hill.—The Jerry Johnson claim on Ironclad hill is reported to be the scene of an important strike; the vein, $3\frac{1}{2}$ ft. wide, assays \$25 per ton across its whole width. Dan Weyand & Co. have sub-leased this ground from Henry P. Dahl. The annual report of the Gold Dollar M. Co. is out and shows a prosperous year; ore produced amounted to 3,217 tons, with a gross value of \$82,100; the royalties on this ore to the company are \$13,637.62. There is \$11,625.70 in the company treasury. There are seven sets of lessees on the property. In the upper workings are large ore reserves; the company is awaiting the completion of the drainage adit, to the construction of which it contributed \$4,000, before it develops the ore-shoots known to extend below water-level. The drainage adit is now in 1,050 ft. and is being driven with all possible dispatch.

Construction work on the Stratton's Independence mill reservoir is being rapidly pushed; the dam across Wilson creek is expected to retain 17,000,000 gal. Practically all the buildings of the mill are under cover and Harry Nelson, Philip Argall's assistant, has moved to Victor in order to personally oversee the installation of the mill machinery, the foundations and building for which have been rapidly erected; A. R. Minner is constructing engineer.—On November 18, the British-American Co., working the South Dante, declared a monthly dividend of \$6,000, the largest heretofore being \$1,000. A new orebody has been discovered on the 500-ft. level during the last week; it is planned to ship two cars per day. A new ore-house is being built and a new hoist, recently ordered from Denver, is being installed. The present management of the Gold Sovereign is being criticized, and an effort will be made at the annual meeting on January 2 to have it changed. O. H. Hinds, of Le Mars, Iowa, holding 135,000 shares, has sent out circulars making sensational charges, which are answered by Mr. Rapp, the president of the company, in a letter to stockholders; the mine is affected by the destruction of the Golden Cycle mill, as much of the ore is low-grade.

The Forest Queen reports a new orebody on the 400-ft. level which assays from an ounce to 12 oz. per ton; this ore-shoot is 4 ft. wide and is but a short distance from the shaft.—The Henry Adney reports another strike on the 500-ft. level, assays from which are more amazing than any heretofore obtained on this property; a sample taken from the muck pile assayed 169 oz., while the breast of the drift has assayed as high as \$1,000 per ton.

Mexico.

A French Criticism.—Boleo Copper Mines.—The Mazapil Copper Co.—El Lustre Becomes a Success.—Suspension of Work.—Good Results at El Oro.—Gold Production.

The closing down of the mines at Cananea has been taken as the basis for a more or less deserved and merited criticism by *Le Courrier*, the French journal of Mexico, of the way in which stock speculators in the United States may thus paralyze an immense industry and bring distress to thousands of homes, and then compare it to the work of the French company in Lower California (the Boleo Copper Co., of La Paz and Santa Rosalia, owned and operated by the Paris Rothschilds),

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

LEASES at Goldfield, Nevada, generally run from six months to a year; the royalty is generally from 20 to 25% on the net smelter returns.

IN A cyanide plant any confusion in regard to weak solutions, strong solutions, and other pipes is easily avoided by painting each of the pipes a distinctive color.

CAMS have been designed with a special involute face so that a speed of 110 drops per minute was safely attained, when the height of drop was as great as seven inches.

FILTER-PRESSES are used at the Silver King mill, Park City, Utah, for concentrating the rich slime from the oxidized silver-lead ore. It is impossible to save the scales of silver chloride on the tables and so the slime is filter-pressed.

THE concentration of gold above water-level is illustrated by these figures from the El Oro district, Mexico: In oxidized ore the ratio of gold to silver is $6\frac{1}{2}$ gm. of silver to 1 gm. of gold; in the sulphide ore the proportion is 15 to 1.

A CUPEL molding machine is used at several cyanide mills for briquetting the precipitate. In this way the loss in refining due to dusting is greatly decreased. Generally a small rectangular mold is substituted for the circular cupel-form.

THE Moore filter-baskets are discharged, in New Zealand, by simply opening a valve, which connects with the atmosphere; the in-rush of air to fill the partial vacuum loosens the cake apparently as effectively as the American practice of blowing compressed air inside the filter-leaves.

LEAD SMELTING was a more important industry in the United States in 1900 than copper smelting; by 1905 copper had become more important than lead smelting; this has been due mainly to the change in American smelting practice whereby 'dry' gold and silver ores are smelted with copper ores as 'gatherers' instead of lead ores.

COST of tube-milling on the Rand is illustrated by the following costs per ton: Glen Deep, 21.28c.; Nourse mines, 10.98c.; Langlaagte Deep, 14.24c.; Simmer & Jack, 13.37c. Due to fine-grinding the recovery has also risen so that it is now at the Langlaagte Deep theoretically 95.79% and actually 96%, at the Nourse Deep 93.40% and 92.97%, at the Glen Deep 93.64% and 93.90%, respectively.

IN sampling rich gold and silver ores, which require fine grinding for proper sampling, the quartering should be done on tables covered with plate glass. A wooden surface is retentive of fine particles of ore, especially particles of metallic gold or silver; an iron surface wears unevenly, and besides scales of it are liable to flake off and get into the sample. A glass surface is smooth, hard, readily cleaned, and easily replaced, if broken.

A SUBSIDENCE occurred recently at the Waihi mine, New Zealand; as the stopes at Waihi are filled with waste as soon as they are depleted, this subsidence only amounted at surface to about two inches. Although the subsidence occurred near No. 1 shaft, this, except for a

slight tightness between the guides, was unaffected. This occurrence helps strengthen the belief that, with moderately careful filling of the stopes, no trouble need ever be feared at surface from subsidence due to underground mining.

AN air-tight door should be placed in the first stretch of untimbered ground near the mouth of all adits so that, in case the surface buildings near the mouth of the adit burn, the door can be closed and the smoke kept out of the mine. This door should be hung so that it will close itself. It should be held open by a wire or rope which leads to the mouth of the adit, so that the door can be quickly closed from surface. Neglect of this precaution has caused the loss of several lives, for instance at the Kearsarge mine near Virginia City, Montana.

MACHINE SHARPENING of drill-steel on the Rand costs \$15.50 per 1,000. Calculating that 1,000 machine-sharpened bits are equivalent to only 860 hand-sharpened bits in wearing ability, this represents a saving on the Rand of 3.7c. per ton of ore crushed. The reason for the greater life of a hand-sharpened bit is probably due to the fact that the hand-sharpened bit is hammered more in the sharpening and therefore has a smaller-grained crystalline structure than the machine-sharpened steel. The bit should not be shaped too quickly by a machine-sharpener; steel is improved by hammering.

ON a gold-bearing mispickel ore at the Deloro mill at Deloro, Ontario, a gold extraction of 88 to 90% was made. The ore was stamped to 40 mesh and then amalgamated, thus recovering 57% of the gold. The pulp was then classified and concentrated upon vanners and tables. The tailing assayed only 2 to 2.5% of the original gold content and only 0.5% of the arsenic content. The concentrate was then treated by cyanogen bromide and 90.5% of the gold was recovered by zinc-dust precipitation. After the gold was extracted the concentrate was sent to the arsenic furnaces where the arsenic was recovered as arsenic white.

MINING litigation arising from the law of the apex has been avoided in the Warren and the Clifton-Morenci districts of Arizona by the interested companies agreeing to bound their orebodies by vertical side and end-lines. This has resulted in a system of development peculiar to these camps. At Bisbee, in developing a level a drift is run, as soon as possible, parallel with, and about 40 or 50 ft. from, any boundary line which separates the property from that of another company. Thus they develop and mine any ore occurring near the boundary, while the ground is still strong, and leave to the neighbor the disadvantage of mining in heavy ground in case the orebody extends beyond the boundary.

WIND PRESSURE varies with the square of the velocity of the wind, but there is as yet no agreement as to the constant in the formula. According to Smeaton, $P = 0.005V^2$; according to Martin, $P = 0.004V^2$; according to Whipple and Dines, $P = 0.0029V^2$; where P is the pressure, when the surface is at right angles to the direction of the wind, in lb. per sq. ft. and V is the velocity in miles per hour. At 60 miles per hour these formulae give the pressure in lb. per sq. ft. as 18, 14.4, and 10.44, respectively. The Smeaton formula is generally accepted as correct for small surfaces such as used in wind-mill practice, but it gives too large results for large solid bodies. The Smeaton formula is used by the U. S. Signal Service. Kidder in his Pocket-book accepts the Martin formula for building purposes.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

Sir—The columns of your well-known journal record the pioneer work done in the early 'nineties on the Pacific coast by Almarin B. Paul, more especially the crushing in stamp-mills of gold ore with weak cyanide solution in place of water. It is somewhat surprising, therefore, that more attention has not been paid since then to the recovery by amalgamation or otherwise of the coarser gold particles in such pulp. While crushing with cyanide solution materially assists in dissolving the gold by means of the agitation, aeration, and thorough contact, yet gold particles of appreciable size do not completely dissolve within the practicable time limit of ordinary cyanide treatment, and are hence liable to be discharged with the residue unless some auxiliary method of recovery be employed. When the gold particles are fine enough to dissolve in a reasonable time, the necessity for amalgamation, of course, does not exist.

Among the published recommendations of a famous California millman—C. H. Aaron—prior to the discovery of the cyanide process, was the steady dripping into the mortar-box of cyanide solution to brighten the plates and gold particles in the ore being crushed. This feature alone would indicate a greater facility for gold amalgamation in a cyanide solution pulp than in a water pulp. The use of ordinary amalgamated copper plates for the above purpose is, however, subject to the disadvantage that both mercury and copper gradually dissolve in the solution and are re-deposited in the zinc-boxes, thus affecting clean-up and refining operations. Concentration of the pulp would no doubt serve to recover most of the coarser gold, but such an equipment seems cumbersome and expensive to install and operate, if solely for the purpose of recovering that fraction of the gold whose chemical and physical condition is such as to most readily insure contact and retention by a mercury surface. At present crushing with cyanide solution appears best adapted for the tube-milling of an ore which has been dry-crushed with rolls and which carries only fine gold. In this case amalgamation is not needed, the difficulty is minimized of accurately determining the value of the ore before treatment, and the small volume of solution in circulation reduces the danger of loss of soluble gold by leakages or overflows. It is to be hoped that the researches of the many skilled and progressive metallurgists of the Western mining States will develop a method of as satisfactorily dealing with a cyanide solution pulp carrying a portion of its values in coarse gold.

City of Mexico, October 6.

VIATOR.

[Prompted by this communication, we wrote to several cyanide specialists, stating the problem as follows:

"Given an ore containing some coarse gold, as well as gold finely divided, what steps would you take to save the coarse gold, which otherwise will escape solution in cyanide?"

To this question we have received several replies, one of which we publish herewith. The others will appear next week.—Editor.]

The Editor:

Sir—Replying to your question:

"Given an ore containing some coarse gold as well as gold finely divided, what steps would you take to save

the coarse gold, which otherwise will escape solution in cyanide?"

1. Should the coarse gold occur in some quantity and the ore is otherwise suitable for crushing in dilute solution, I would proceed as a first step to amalgamate it in the mills or batteries, and on copper plates. The small amount of mercury soluble in say 0.02% KCN solution will, as cyanide of mercury, greatly accelerate the solution of the fine gold as well as improve the precipitation of the precious metals in the zinc boxes.

2. When the ore is crushed in water, plate amalgamation will usually take care of the coarse gold, while the separated slime and sand can be cyanided in the usual manner.

3. A satisfactory modification of 1 and 2 is to pass the ore, crushed either in cyanide solution or in water—but preferably the former—through a spitzkasten, so as to draw off the coarse gold with a small amount of concentrate. This product should then be ground and amalgamated in pans, and where the crushing is conducted in cyanide solutions the overflow from the pans can, after passing a precautionary settler, join the main mill-stream and pass direct to the extraction plant. In this way (No. 3) the amalgamation of the coarse gold, even in a large mill, can often be quite satisfactorily and economically conducted in, say, two pans. Further advantages might be pointed out, such as the benefit to be derived from the finer grinding of the concentrate, and where cyanide solution is the medium, much stronger solution than 0.02% may be used, without excessive mercury loss. Crushing in cyanide solution has come to stay, and with the additional feature of amalgamation, will take care of both the coarse and fine gold in the direct treatment of perhaps the majority of gold ores. I advocate strongly the removal by amalgamation of all the coarse gold instead of fine-grinding to render it readily soluble in cyanide. Plate amalgamation is quite feasible, but the solutions should not exceed 0.02% cyanide, otherwise both mercury and copper are too freely dissolved. Where crushing and amalgamation in cyanide solutions is practised, ordinary precautions must be taken against loss of solution. The mill-floors should be constructed of cement saturated with tar on the surfaces, or better still, of asphaltum, with, in either case, gutters to conduct all drainage to a central sump.

4. In dry-crushing mills, the coarse gold can be recovered from the leached sand.

(a) By sluicing them over riffles.

(b) By placing a spitzkasten in the tail-sluiice.

The concentrate from either (a) or (b) should be ground and amalgamated in pans or Chilean mills, as it will contain all the coarse gold.

I used the (a) method quite successfully for several years in a large dry-crushing and roasting plant. In that case the sluice was 300 ft. long, 20 in. wide, and set at an inclination of 1 in 16; the bottom was filled with iron riffles; 60 tons of sand and 100 tons of water per hour passed through the sluice. The riffles were cleaned up once a week, when the first 50 ft. usually gave 90% of the coarse gold in a concentrate carrying from 5 to 10 oz. gold per ton. The last 50 ft. of the flume did not show a trace of coarse gold but gave a concentrate of partially roasted ore, assaying about 0.15 oz. per ton. The total product from the riffles amounted to about 2% of the weight of tailing passing through the flume.

The final tailing discharged on the dump averaged 0.065 oz. gold per ton, but nothing further could be profitably removed by concentration, without finer grinding, as was amply demonstrated to certain parties who later erected a large plant of Wilfley tables, etc., at a cost exceeding \$50,000; this plant, however, being an unqualified fail-

ure, was dismantled and removed after a few months' trial of these dumps. I believe then, that the sluice and riffle must be admitted to be an effective means for the removal of coarse gold from sand, and under proper conditions I prefer it to spitzkasten. Blankets, sheep-skins, and such like are time-honored, though antiquated means for catching gold and concentrate in flumes, streams, and on tables, so that a minimum quantity of material containing practically all the coarse gold can be submitted to a grinding and amalgamation process. Amalgamating all the crushed ore, when low-grade gold ores are crushed in cyanide solutions, is seldom either necessary or expedient. A riffle or spitzkasten concentrate will usually contain all the coarse gold not amenable to cyanide, and the cost and trouble of amalgamating 90 to 95% of the ore is eliminated. Along these lines I look for the next great advance in the metallurgy of gold ores. My ideas may be summarized as follows:

(c) The substitution of weak cyanide solutions for water in the crushing apparatus, circulating the mill solutions in a closed system.

(d) The removal of the coarse gold in a concentrate by riffle or spitzkasten.

(e) Amalgamating the coarse gold in pans and similar apparatus.

By 'coarse' gold in this article I mean metallic gold that by reason of its size or for other causes escapes solution in ordinary cyanide treatment. I further assume that it can be collected in a small amount of concentrate, and my experience shows this assumption is well founded.

PHILIP ARGALL.

Denver, October 14.

Questions by a Practical Miner.

The Editor:

Sir—The letter in your paper of November 9 purporting to be from a practical miner is so evidently unjust that I am going to dignify it by answering. The mine in question has a steam-driven compressor plant at its old mill, so that should, by any manner of means, the new plant break down, we could still keep mining. Again, the power-plant in question is a tandem-compound Corliss belt-driven generating set. While there is a possibility, there is hardly a probability of its breaking down, as it has 50% excess power over what is required. Further, a hydro-electric plant on the river two miles away would have cost three times as much as the steam plant, as there are no roads and the country is too precipitous, besides taking twice as long to install. This was decided by an electrical engineer at Los Angeles, of national reputation.

If it was necessary to put in a duplicate steam-generating set, why should it not be necessary, and even more so, to put in a duplicate hydro-electric plant, transmission lines, etc., where the floods are as serious as in the American river. Again, the wood fuel costs little, as only white fir and cedar, which are no good commercially, are burned, together with the slabs from our own saw-mill. That part of the letter relating to the "practical miner" and the quartz outcrop is so ridiculous, if you knew the truth, that it is not worth answering. I have had 25 years actual mining experience from chuck-tender to mine-foreman, and then superintendent from Rosslund to Arizona, and I have never seen two Corliss or electric hoists on a shaft, for fear of the breaking down of one. Duplicate compressor-plants for the same reason; duplicate engines in either a concentrating or stamp-mill, for the same reason. But what I have seen, where the man in command knew his business, was a reserve steam plant to back up any failure of the hydro-electric plant,

where the mine and mill depended on the latter. Does it make any difference which is installed first? If the mine development is waiting for the central power station, I would think it logical to install the quickest generating set. If this was a main power-plant for selling power, then the idea of three engines might be good. As the life of any mine is limited, why go to this expense, especially if it is not justified? I have also on occasion been accused of being a 'practical' mine manager. Perhaps I get it from not discussing in print, on hearsay, only what I thought were the mistakes of the other fellow. Rather let us see with our own eyes and discuss the points with the man in charge than rush into print with garbled information.

The writer welcomes criticism of his mining or management at any time, if he makes mistakes and if this criticism comes from an engineer with more experience than himself, but he does resent your publishing information which is unjust, erroneous, and given by a man never on the ground and certainly not a 'practical miner.'

Westville, Cal., November 13.

[We are glad to insert this letter. The one to which it refers was not published without a foot-note demurring to some of the inferences.—Editor.]

Wall Street.

[A copy of the following letter has been sent to us. We are glad to publish it.—EDITOR.]

Mr. Robert Schorr,
61 Fremont St., City.

Dear Sir: I have your letter of the 18th inst. in which you refer me to an editorial on page 598 of the last number of the MINING AND SCIENTIFIC PRESS, entitled 'Wall Street.' As stated by you in your letter, the editorial in question "hardly suits my views." I agree with our editor in regarding the popular idea of Wall Street as a slander, and in believing that "populist orators may be responsible for such a slander, but there are reasons less superficial."

I differ with him, however, in his analysis "of this prejudice against Wall Street," for prejudice it undoubtedly is. Our editor asks, "Is it merely the expression of ignorance or due to a jealousy of those that pull the strings?" He thinks it is neither of these, but that it is due to the fact that those citizens of various communities who are distinguished for wealth and initiative are absorbed by Wall Street and become mere gamblers.

As I see it, his explanation takes it for granted that Wall Street is a centre of gambling, and that those who have offices or operate in the Wall St. district are mere gamblers, and that their labors are lost to productive industries. This is the part of his editorial that I am not willing to grant. In order that we may have a common starting point, let us consider for a moment what Wall Street really is. Under the National Banking Act the banks of the country may be divided into three classes: (1) Country banks, (2) reserve city banks, and (3) central reserve city banks, all of them being required under the law to carry a certain percentage of reserve funds against their deposits. They differ in that the reserve of the country banks may be carried partially as lawful money and partly as deposits in reserve city banks, while the reserve of the reserve city banks may be similarly divided between lawful money and deposits in approved central reserve city banks. The immediate result of this system is to cause the reserve cities, such as San Francisco, to be the financial mentor of the towns tributary thereto, and at the same time to cause reserve cities, such as San

Francisco is, to be tributary to the central reserve cities. In other words, the United States National Banking Act provides that certain cities of the country shall be pre-eminently the money and credit centres of the country.

Of these central reserve cities, New York is naturally the largest and most important, due to many natural causes, of which we may mention its being the largest and oldest central reserve city, and its being the gateway to Europe and a large portion of the civilized world. Being by law and by natural causes the money and credit centre of America, it follows of necessity that New York is the financial centre of the country.

Being the financial centre, it follows that New York is the most convenient and necessary location of the fiscal offices of the large corporations of the country. Being the money and credit centre of the country, and at the same time the centre of the fiscal operations of our large corporations, it follows that New York is the greatest security market of America. In this way we are forced to the conclusion that New York City is by law and by common consent the centre of banking, of corporate fiscal operations, and of security trading in so far as America is concerned. As the banking business is intimately connected with the financing of new enterprises, it is not surprising that by far the greater portion of such new undertakings are financed from the head and fountain of the banking business.

In New York the various institutions established to facilitate the operations above mentioned are to a large extent confined to the lower end of Manhattan, and it is this part of the city that is known throughout the country as Wall Street, so called because of the fact that Wall St. itself is the centre of these activities. The institutions which make up Wall Street are the banks, the New York Stock Exchange, and the fiscal offices of the large corporations.

The so-called Curb market, although an integral part of Wall Street, as popularly understood, is but as a drop in the bucket, and is not, in reality, an important part of the great financial community centred about Wall and Broad streets. As our editor will doubtless admit that neither the banks nor the corporation offices are gambling institutions, we may confine our attention to the New York Stock Exchange. It is my personal judgment that much, if not most, of the prejudice regarding this institution has come about through the misconception that this institution differs from the bucket-shops throughout the country only in size. No more ignorant injustice nor a more malicious misrepresentation could be perpetrated against any institution.

In the first place, the members of the exchange operate under an extremely stringent set of rules, which are administered absolutely without fear or favor. Under these rules every sale or purchase of a security on the floor of the exchange is as much a *bona fide* transaction as it is possible to make a transaction *bona fide*. It is true that many transactions are cleared one against the other in the same manner that bank checks are cleared in the clearing houses, but does this make a gambling transaction?—if so, we are all gamblers, except the inhabitants of the poor-houses. Do you call a man a gambler who issues a check not knowing for certain that the check will be turned into lawful money? Most certainly not. Is it the *bona fide* purchase of securities on margin to which our friends object? Do they call buying goods on time, gambling? Is it fair to say that the man who buys steel common on time is a gambler and the man who buys potatoes at ninety days is not? They both buy with the same object—to make a profit; and at the same time, to tie up as little working capital as possible. Or, is it *bona fide* 'short selling' upon which their wrath is

centred? Is the manufacturer who sells his output for delivery in ninety days a gambler? Should he be classed with the farmer who sells his crop before it matures, or the man who sells securities for future delivery? As to the underwriting syndicates, isn't it as legitimate and as honest to buy securities in bulk and to retail them at a profit as it is to buy and sell merchandise in the same way? If we are to call these transactions gambling, then we are forced to admit that all business is upon a plane with faro and roulette. If one defines gambling as a risking of capital, then all business is gambling; but this is not the definition of gambling. As I see it, gambling is the act of hazarding wealth upon mere chance; as opposed to hazarding wealth upon mature judgment, which is a legitimate business transaction. Under this definition, the operations of the New York Stock Exchange—that is to say, the purchase and sale of securities and credits—is as legitimate a business transaction as is the purchase and sale of commodities. No one would contend for a moment that there are no rascals in Wall Street, no more than he would that all grocers are honest; yet I do maintain that there is nothing inherently dishonest or nothing in the nature of gambling in either the business of a Wall Street operator or that of the grocer. For a green country boy to undertake to operate the largest grocery in San Francisco without studying the problems involved is gambling, just as it is for a man to innocently saunter into Wall Street in the same spirit. It is just this view of the stock market that brings about the shearing of the lambs. Were I to define a lamb, I would say that he is a man who speculates in Wall Street *believing that he is up against a gambling game*.

In order that my position in this matter may not be misunderstood, it may be well to state that I do not speak as an insider, for I have never purchased a security on margin, nor have I ever traded in a bucket-shop. I speak merely as a man who believes with all his soul in fair play.

A. G. McLAUGHLIN.

San Francisco, November 23.

NEW COLOMBIAN RAILWAY.—The contractors for the railway now under construction from a point on the Magdalena river to Bogota, have instructions from the company in London to complete the road to its terminals by the end of the present year, if possible, but owing to the conditions and the damage done to the part of the road already built by the recent storms, requiring extensive repairs on that part, even to the point of considerable rebuilding, it is considered impossible to carry out the instructions as to time, although the work is being pushed forward vigorously. There are still 35 of the 171 km. (kilometre = 0.62 of a mile) to be built, and when completed this line will give the Railway Concession & Contract Co. of London, which has also purchased the railway from Cartagena to Calamar, and the boats of the Fluvial Steamboat Co. on the Magdalena river, a direct line from the port of Cartagena to the capital of the Republic. The company is also considering the future construction of the railway connecting the Magdalena with Medellin, which road would tap one of the richest mineral districts of Colombia. There are 80 km. of this road completed, but there remain about 160 km. to build.

MALAYSIAN TIN.—The following statement shows the output of tin from the Federated Malay States for the first four months of the year 1907. The figures represent tons of 2,240 lb. Perak, 8,187; Selangor, 5,067; Negri Sembilan, 1,386; Pahang, 623 tons. Total, 15,263 tons, a falling off from last year's output of 204 tons.

Measuring Industrial Temperatures.

Written for the MINING AND SCIENTIFIC PRESS
By THOMAS T. READ.

Few subjects excite a livelier present interest among scientific men engaged in industrial work than the accurate measuring of temperature. With a growing recognition of the important influence of apparently slight changes of temperature in many well-known processes, and the tendency to secure economy of operation by ascertaining the conditions necessary to secure the maximum efficiency of operation, has come a desire to be informed as to the apparatus and methods available for the ready measuring and recording of temperature, under industrial conditions. To this desire is traceable the recent rapid growth of commercial pyrometry, or the measurement of temperatures above the ordinary range.

The characteristics that a pyrometric instrument must possess are easily stated. In the first place it must possess the degree of accuracy commercially required. All the recent types of instrument are perfectly satisfactory in this regard, and many possess an accuracy sufficing even for the most exacting demands of scientific work. It must also remain accurate with constant use. Many instruments that are satisfactory in every other regard fail in this requirement, either necessitating constant re-

Fig. 1.—Principle of Resistance Pyrometer.

standardization or else slowly burning out with long exposure to a high temperature. In addition, the pyrometer should be simple and easy to use, so that it is not easily injured or put out of adjustment. It should be capable of making a continuous record, for in many cases the chief use of pyrometric determinations is the securing of uniformity and constancy of operation.

Passing over the liquid and gas thermometers, which in their present state are adapted to measure fairly high temperatures, but which are not generally fitted for industrial conditions, and are not capable of making a continuous record, we come to the pyrometers that make use of the differential expansion of an iron-carbon rod under heating. These were used to some extent a few years ago, but they are no longer regarded with favor. They possess all the disadvantages of the mercury thermometer, except liability to breakage. With continued use the iron rod becomes permanently expanded, and the scale no longer reads correctly.

An early type is illustrated by the Seger cones. These are slender cones of refractory materials, china clay, quartz, etc., the composition of the mixture being so ad-

justed that it fuses at a given point. By using a series of cones of graded composition, a scale of temperature is obtained. A cone is considered to be fused when its top bends so as to point directly downward. Like the pneumatic rock-drill, Seger cones are theoretically unsatisfactory, but in practice they are better suited for use in their own particular field than any substitute. They measure a rising temperature only; the fusing point is affected by the rate at which the temperature rises and by dust and the gases of combustion. Nor is it possible to obtain a continuous record, but because they are of similar composition to the material being heated in the manufacture of clay products, and consequently both are similarly affected, they are satisfactory in spite of their inaccuracies, and therefore this type of pyrometer remains in common use in the manufacture of porcelain, china, earthenware, and brick. Recently more accurate methods have been introduced.

Several types of pyrometer depend in their action upon specific heat. The Siemens pyrometer was practically a calorimeter. A ball of the proper size was placed in the furnace and allowed to come to the same temperature. It was then removed and placed in a known quantity of water, and from the rise in temperature of the water the temperature could be computed. The objections to this are obvious. Another method is to lead water with a constant rate of flow through the furnace in an iron tube. By measuring the temperature of the inflow and the outflow, the temperature of the furnace is easily computed. In the ordinary application of this method the computation is done mechanically. The inconvenience attending the use of this apparatus is also apparent. A method which has found some application to the measuring of the temperatures of hot blasts is to divert a small portion of the blast through an apparatus somewhat like an injector, so proportioned, usually, as to take in three or four times as much outside air as there is blast. The temperature of the resulting mixture is given by an ordinary thermometer. From this the temperature of the blast is obtained. It is seen that slight variations in the temperature of the outside air will make large errors in the apparent temperature of the blast. The device is not especially convenient to use, and cannot be made recording, hence the use of it is limited.

Electrical resistance pyrometry is of wide application in England, but has not been received with much favor on the Continent or in the United States, where the thermo-electric methods are now generally preferred. In the resistance method a coil of platinum wire is exposed to the heat, the increase in the resistance is proportional to the temperature. The variation in the resistance is measured by means of a Wheatstone bridge, this latter being generally so calibrated as to read directly to degrees. The taking of a reading includes the introducing of the coil at the point where the temperature is to be measured, allowing it to remain there sufficiently long to attain the same temperature as the furnace, and the bringing of the bridge galvanometer to balance by adjusting the resistance. The temperature is

Fig. 2.

then read directly from the scale. The construction and operation of the instrument is seen from the accompanying illustrations, taken from the catalogue of the Cambridge Scientific Instrument Co. The principle of the instrument is easily understood by reference to Fig. 1. At *A* and *B* are shown the two compensating lead wires, introduced so that unequal heating of the leads may not affect the reading, the temperature read is therefore that of the coil. The temperature scale is on the bridge wire marked *D*. In the instrument as intended for use, galvanometer, bridge, etc., are within a portable carrying case, and the coil is within a refractory tube; the leads connecting this to the indicating instrument may be made as long as desired. For permanent work in one position the bridge, etc., are arranged to be attached to a wall, or other convenient object, and the instrument can then readily be made to keep a continuous record.

In Fig. 2 are seen the details of the construction of that part which is exposed to the action of the fire. The coil is wound as shown, upon mica discs, and the compensating leads are also shown. The porcelain tube is likely to become broken from rapid changes in temperature, and if the heat of the furnace is not too high a steel tube may be substituted. This latter is somewhat

Fig. 3.—Thermo-Electric Pyrometer.

permeable to furnace gases, however, and as these are injurious to the platinum, in cases where they are likely to cause injury, an outer steel sheath and an inner porcelain one may be combined with advantage.

The objections to this method are the same as those given for the thermo-electric. It has no 'cold junction' as with the latter, but the batteries need attention to make sure that they have not become polarized, the possible error in this method being much more serious than with the former. The recorder is more complicated than that required for a thermo-electric couple, and does not cover as wide a range. Temperatures can be measured up to the softening point of platinum, but the makers do not recommend this type of instrument for continuous use above 900°C ($1,650^{\circ}\text{F}$). For accurate scientific work a potentiometer is generally used in place of the bridge. With proper precautions, electrical resistance is the most accurate method of measuring temperature. The bolometer, an instrument using this principle, will detect a difference of one-tenth thousandths of a degree.

The thermo-electric pyrometer is the method now most generally used in the United States. This instrument depends upon the fact that if wires of two dissimilar metals are connected through a galvanometer at one end, joined together at the other end, and the junction heated, an electric current will flow through them and be shown by the deflection of the galvanometer, the amount of

deflection being dependent upon the difference in temperature of the two ends of the wires, and also upon the nature of the wires. Suitable pairs of wires for this purpose are platinum and platinum alloyed with 10% of rhodium or iridium; platinum and silver; iron and nickel; copper and nickel; copper and an alloy of copper with 25% nickel, known as constantan; and various others. Ordinarily the copper constantan and platinum-rhodioplatinum couples are amply sufficient, as the latter will measure from 300°C up to the softening point of platinum, and the former from 500°C down to the lowest temperatures commercially attainable. Couples containing iron should be used with care, as above the change points in the iron they are necessarily inaccurate. These base-metal couples will not stand exposure to a high temperature, as oxidation seriously affects the readings.

This method is diagrammatically shown in Fig. 3. The galvanometer is of the suspended coil type, it is very delicate, and, consequently, requires careful handling. It should be carefully leveled before releasing the needle, and should never be moved while the latter is free, as this is likely to cause damage to the suspension. Before taking a reading it is necessary to make certain that the galvanometer needle reads zero when no current is passing; if this is not the case it is made to do so by moving a small projecting pin at the top of the suspension spindle. It must be kept in mind that what the

Fig. 4.—Fery Radiation Pyrometer Telescope.

galvanometer indicates is not the temperature of the junction, but only the difference in temperature between the hot and cold ends, consequently an allowance for the temperature of the cold end must be made in order to obtain the real temperature. Most of the galvanometers as supplied by the makers, tend to confusion in this regard, as they are calibrated to degrees as well as to millivolts. For rough work, where the couple is so long that the cold ends remain at the temperature of an ordinary room, the use of the scale on the face of the instrument will not cause serious error, but if the couple is short, or the construction of the furnace is such that it is impossible to prevent the outer ends of the couple from becoming heated, it will be necessary to measure the actual temperature of these ends, and make an allowance. With the copper-constantan couples the temperature of the cold ends is simply added to that corresponding to the deflection observed. In the case of the platinum-rhodioplatinum couples only one-half this temperature must be added, as these couples are only half as sensitive in their lower ranges as they are above. For a slight fee couples will be calibrated by the National Bureau of Standards at Washington, which will furnish a table of temperatures corresponding to deflections, throughout the range of the instrument.

It should be observed that the 'cold junction' is not where the wires are connected to the galvanometer, but where the couple wires are joined to the copper con-

ductors. The most convenient way to keep the junctions at a constant temperature is to immerse them in water containing ice, short-circuiting through the liquid being prevented by enclosing one of the wires in a glass test-tube. A convenient way when using the base-metal couples is afforded by the Bristol compensator, shown in Fig. 3. This is a platinum loop partly immersed in a tube containing mercury, the expansion of which is made to cut sufficient resistance out of the circuit to compensate for the increase in temperature of the cold ends.

The copper wires connecting the couple to the galvanometer should be amply large, otherwise their resistance will affect the deflection. Ordinary electric light cord serves very well for all ordinary lengths. When the proper connection to secure deflection in the right direction is secured, it is well to tie a knot in the cord going to the right hand binding post, or mark the connections in some way to save time in connecting afterward.

The three most important points in the use of the thermo-couple are to prevent short-circuiting, to protect the wires from the effects of hot gases, and to insure that the thermo-junction is brought up to the temperature of the furnace. The first is secured by passing the wires through double-bored clay tubes, $\frac{1}{8}$ in. diam., down to within three or four inches of the junction. A narrow strip of ordinary stove mica is then placed between the wires and a single-bored clay tube is slipped over them. To secure the second, it is necessary to enclose these tubes in another tube sufficiently long to pass completely out of the furnace, and sufficiently impervious not to let the furnace gases pass through it. If the temperature is not high, wrought-iron pipe (such as gas-pipe) is satisfactory. The pipe should not be capped on the inner end, but should be welded shut. With continued use it will become oxidized, and will need to be renewed. For high temperatures porcelain is ordinarily used, but it is likely to break from the sudden changes of temperature, or from shock; and in many cases, as in taking the temperature of molten baths of metals that alloy with the platinum, the breaking of the outer tube will cause the destruction of the couple. A better substance for this purpose is fused quartz tubing. This has practically no co-efficient of expansion, less than one-twentieth that of porcelain; consequently, it can scarcely be broken by heat. It is sufficiently resistant to use in molten baths, and is also cheaper than the porcelain. It can be obtained in any size. A quartz tube obtained by me from the Wilson-Maeulen Co. of New York has been subjected to trying conditions with entirely satisfactory results.

The necessity for protecting the wires of the couple from the furnace gases is due to the fact that there are slight impurities that are reduced by the action of the gases, and these produce a harmful effect such as they do not possess in their oxidized state. The necessity for protecting the wires from a metallic bath is obvious. If the wires have been strained it is necessary to anneal them; this is easiest done by passing a current of sufficient strength to heat them red-hot.

It is necessary to take proper care in introducing the junction into the furnace to obtain correct readings. The galvanometer will record the temperature of the junction with an accuracy far greater than required. But by improperly placing the couple, the reading obtained may be so far different from that which should be obtained as to render the results valueless. It is sometimes impossible to place the junction at the point desired. The point selected may differ to a surprising degree. In some experiments made in my laboratory a thermo-couple was introduced at the throat of a small reverberatory furnace, having a hearth area of about two and one-half by

four feet. When the thermo-couple read 750°C , temperatures were read on various points of the hearth with a radiation pyrometer. It was found that the hearth temperature varied from $1,050^{\circ}\text{C}$ near the bridge-wall to 750°C at the couple. This instance will serve to emphasize the importance of placing the thermo-couple at the point where the temperature is desired.

The thermo-couple is useful for a wider range of work than any other pyrometer. The platinum-iridioplutonium couple gives a more open scale than the platinum-rhodioplutonium, but can be used only up to $1,400^{\circ}\text{C}$, while the latter can be used up to $1,600^{\circ}\text{C}$. But if either of these couples are used continuously near their upper limits they will slowly deteriorate, the iridioplutonium by a slow distillation of the iridium out of the alloy wire into the pure one; the rhodium couple probably from the effects of the furnace gases. The point most apt to be neglected in practice is the proper protection of the wires from the furnace gases, and as the couple is expensive, lack of care in this regard proves costly.

For continuous service above $1,500^{\circ}\text{C}$, thermo-electric pyrometers are useless, and they are not satisfactory for ranges much below this, especially in certain places. The only pyrometers that are successful for these upper ranges are optical instruments. These are of two classes, those that depend on the photometric measurement of the light emitted by the hot body, and those that measure the heat radiated by it. There are several types of the former, but none of them are useful from the industrial point of view. In all of them the light emitted by a body is compared, either directly or indirectly, with the light of a standard lamp. In works practice the observer has neither time nor patience to make exact comparisons with standards; therefore, although these methods are capable of giving exact results in the laboratory, in works the determinations made by them are usually seriously wrong. In checking up with a radiation pyrometer some determinations made in a roasting furnace with a photometric pyrometer, it was found that the determinations of the latter were some 200°F in error at $1,600^{\circ}\text{F}$. One photometric instrument, which has received a good deal of attention, but which is especially unsatisfactory from the works point of view, is the Wanner.

The only remaining pyrometer of industrial importance is the Fery radiation pyrometer, which determines the temperature of a hot body by measuring the heat it radiates. This is based upon the law of Stefan and Boltzmann, that the energy radiated by a hot body is proportional to the fourth power of its absolute temperature. The construction of the instrument is shown in Fig. 4. The radiant energy of the hot body is received upon the mirror *M* and is reflected and brought to a focus upon the hot junction of delicate thermo-couple contained within *D*. Thus, in a manner somewhat similar to the operation of the burning glass, the temperature of the junction of the thermo-couple is raised, and by properly calibrating the galvanometer in circuit with the thermo-couple, the temperature of the hot body is read directly. On sighting through the telescope at the body whose temperature is to be measured, it is seen as two dissimilar halves until the mirror is brought to the proper focus by turning the thumb-screw, when the two halves will coincide. The only limitation as to the distance of the telescope from the hot body is that it shall be sufficiently near so that the image of the body in the telescope completely covers the thermo-junction; in practice this is about a yard for each inch in diameter of the body. With a large hot body it is thus easy to get far enough away from it so that the observer does not get burned, a rather necessary precaution in the case of large roasting

furnaces, fire-boxes of boilers, copper converters, etc. As ordinarily constructed the instrument measures up to $2,000^{\circ}\text{C}$ with an accuracy of 1%. By substituting a galvanometer of the proper resistance it has been used to measure the temperature of the sun ($7,800^{\circ}\text{Centigrade}$).

For the higher ranges of temperature this is the only satisfactory pyrometer for industrial work, and is more satisfactory than any other for many classes of work down as far as it will read accurately, which is about a dull red heat (500°C or 900°F), where, however, the radiant heat is forced to pass through clouds of smoke or dust. On their way to the mirror low results will be obtained, due to the absorption of the radiant heat.

For determining the temperature in various parts of large roasting and casting hearths, fire-boxes, and porcelain kilns, and for determining the temperature of pots of molten metal before casting, I have not found any other pyrometer to compare with it in ease, quickness, and accuracy of observation. I have used it to determine the variation in the temperature of rabble shoes in their passage through the furnace. For permanent use the telescope is best sighted on the bottom of a fireclay tube set in the wall of the furnace, and in such case the mirror must be protected from dust. This is easiest done by completely enclosing the whole instrument.

Too much emphasis cannot be laid on the great saving effected through securing accuracy and economy of operation by the keeping of an accurate and constant record of the temperature of metallurgical operations. There is no better method of overcoming the irregularities of the night shift than a recording pyrometer. In one case known to me the output of a spiegel furnace increased 10% when the men learned that a recording pyrometer had been installed. In another case, where regenerators were used there was a perceptible saving from regularity of manipulation of the valves, as soon as the men learned that any irregularity was unerringly recorded. Similar instances might be multiplied, but it scarcely seems necessary to justify the statement that industrial pyrometry is one of the subjects of greatest present importance in the commercial world.

SOME new points have recently been emphasized regarding the conditions necessary to restore power from a moving car to the line, when single-phase electric motors are used on the cars. These are that the pressure generated by the motors must be greater than that of the line, and this pressure must be under control. There must, of course, be some power-consuming device on the line to take care of the power thus produced. The single-phase motor has characteristics which make it possible to meet these conditions. To obtain complete control of the system, a constant-potential characteristic of the motors operating as generators is desirable, and the motors must be able to run as generators when the relations between field and armature currents are not those which would obtain if they were operating as motors. In other words, it may be necessary for the armature current to be different from that in the field coils, and the commutating conditions will therefore not be those which would exist if the machine were running as a motor. Commutation under these conditions must for this reason be provided for, if successful regeneration is to be obtained. The single-phase motor has a compensating winding which takes care of commutation, and the constant-potential characteristic is obtained by separately exciting the motors, which may be done by reserving one motor of the equipment as an exciter, or by providing some independent source of excitation. Control of the potential generated by the equipment is obtained easily by means of a regulating transformer.

Slime Treatment.

In our issue of November 9, we published a letter from Mr. Askin M. Nicholas, sent by him to us under date of July 5, 1907, from Talmalmo, in New South Wales. In that letter he referred, modestly enough, to his invention of a machine for filtering slime and his bad luck in getting it introduced successfully into milling practice. We published the letter and a part of the drawings accompanying his specifications for patent. Since then it has been pointed out to us that the patent is an important one and interesting to cyanide specialists. Therefore, we now publish the text of the specifications forming part of Patent No. 619,211, granted by the

United States Patent Office to Mr. Nicholas in February, 1899. The reference to the use of air under pressure in the treatment of "adhesive material, such as clay," is important. The text (without any corrections) follows:

FILTERING APPARATUS FOR SEPARATING GOLD AND SILVER BEARING SOLUTIONS.

Specification forming part of Letters Patent No. 619,211, dated February 7, 1899.

Application filed November 11, 1898. Serial No. 696,416. (No model.)

To all whom it may concern:

Be it known that I, ASKIN MORRISON NICHOLAS, mining manager, a subject of the Queen of Great Britain, residing at Bulong, in the British Colony of Western

Australia, have invented an Improved Rotating Filtering Apparatus Principally Applicable for the Separation of Gold and Silver Bearing Solutions from Tailings, Slimes, and the Like, of which the following is a specification.

This invention has been devised for the purpose of providing means whereby solids or insoluble material may be separated from liquids carrying same in suspension, but more particularly for the purpose of providing means whereby the separation of gold and silver bearing solutions from tailings, slimes, pug, or pulverized ore may be carried on continuously and in such a way that a clean or partially clean filter-cloth will be continuously brought into operation without necessitating stoppages for recharging, as required with the appliances at present in use.

The essential feature of the invention consists in the use of a rotating wheel, disk, or table formed with a series of air-tight compartments covered with cloth or other filtering material supported upon a metal screen or perforated plate and adapted to be automatically placed in communication with a vacuum-pump in turn for a sufficient time to enable the liquid to be drawn through the filtering material, leaving the solid constituents upon the filtering-surface, whence they can subsequently be removed by brushes, jets of water, scrapers, or similar contrivances, provision being made for automatically allowing air to enter into the various compartments at the desired period of the operation to facilitate the removal of the solids from the outer surface of the filtering material.

The invention will more readily be understood by reference to the accompanying drawings, in which—

Figure 1 is a vertical central section, and Fig. 2 a vertical transverse section, of a rotating filter constructed according to this invention. Fig. 3 is a cross-section through the rim of the rotating filter on line 3 3, Fig. 1, the scale being enlarged. Fig. 4 is a transverse section on line 4 4, Fig. 2, upon an enlarged scale, illustrating the construction of a valve hereinafter described. Fig. 5 is a front elevation of a modified form of my invention. Fig. 6 is a vertical transverse section on line 6 6, Fig. 5. Fig. 7 is a front elevation, upon an enlarged scale, of the inner face of the valve used with this form of apparatus; and Fig. 8 is an end view, upon an enlarged scale, of the shaft or spindle, illustrating the arrangement of certain ports or passages therein.

The same letters of reference indicate the same or corresponding parts in all the figures.

The arrangement illustrated in Fig. 1 to 4 consists of a wheel—say twelve feet in diameter and four feet breast—mounted upon a shaft A, rotating in bearings B. This wheel may be driven at a speed of, say, from one to five feet per second at the periphery by worm and worm-wheel gear C or otherwise. The wheel is made with a number of compartments on its periphery (marked D to D7), each communicating with one of the hollow spokes E and covered with filter-cloth F or other material resting upon a screen G, of wirework or perforated sheet metal.

Each of the hollow spokes E is in communication through ports or passages *e'* in the axle A with a stationary valve H, communicating through a suction-pipe *h'*, with a suction-pump. This valve H is constructed and arranged, as illustrated in Fig. 4, so as to place only two of said hollow spokes E in communication with said suction-pump at the same time. Said valve is provided with a small air-admission cock I, whereby air may be admitted to each hollow spoke in turn as it passes said valve. This enables the solid material to be more easily removed.

J represents a distributing-laundry for feeding the slimes, tailings, or other material onto the filter, while K K represent perforated water-supply pipes whereby jets of water may be delivered onto the filtering medium in order to remove the solid particles therefrom. L L represent brushes which can also be used for this purpose.

In using the above-described apparatus the material to be filtered or from which the liquid is to be extracted is fed by the laundry J onto the upper part of the wheel—say, for instance, onto the compartment D. As the wheel continues to rotate in the direction of the arrows shown in Fig. 1 this compartment will be placed in communication through its spoke E, port or passage *e'*, and the valve H with the suction-pump, whereby the gold and silver bearing solution or other

liquid will be drawn through the filter and delivered into storage-tanks or elsewhere, leaving the solid constituents on its surface. This operation will be continued until the material has been carried around through about one-fourth of a revolution of the wheel, when the valve H will shut off the compartment from the vacuum-pump, and the solid material can then be removed by washing or brushing it off the surface. This operation can be assisted by the admission of air through the valve I, and if adhesive material, such as clay, has to be treated air under pressure can be forced into the compartment through said valve, as will be readily understood.

Where necessary, water may be added to the partially-dried slimes or other material while on the surface of the filter and be drawn through into the vacuum-chambers in the wheel, so as to still further impoverish the residues.

The invention is also applicable for the recovery and reuse of water from ordinary battery-tailings. In such a case there is no necessity to use water-jets to remove the sand from the filter, as it does not adhere closely thereto and can be removed by brushes alone.

In the arrangement above described the sludge is shown as distributed upon the top of the wheel; but it is obvious that the slimes or other material can be brought into contact therewith at any desired part. For instance, the arrangement illustrated in Fig. 5 and 6 may be used, the various vacuum-compartments being formed in sections upon the face of the disk or table instead of on the periphery and the slimes being fed onto it through jets J, as indicated in said figures. In this arrangement the wheel is shown as being driven by an endless rope C instead of the worm and worm-wheel gear above described; but it is obvious that any convenient form of driving-gear may be employed.

In operation the flow of pulp onto the rotating filter is continuous from the vessel in which it is stored. The speed of the filter and the rate of supply thereto are regulated so as to keep the film of solid material just sufficiently thick as not to resist the external atmospheric pressure.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is—

1. In a filtering apparatus, the combination with a rotating wheel having a series of peripheral compartments covered with filtering material upon their outer, or circumferential faces, each compartment communicating by a hollow spoke with a separate passage in the axle or shaft, an exhaust-pipe with which a part only of the latter passages have communication at the same time, and means for feeding the material to be filtered upon the upper portion of the revolving wheel, substantially as described.

2. In a filtering apparatus, the combination with a revolving wheel having peripheral closed compartments and provided with a circumferential covering of filtering material, of an exhaust-pipe having one end open to a portion of the wheel-shaft and successively communicating with separate longitudinal passages in said shaft as the wheel revolves, a series of hollow spokes leading from said shaft-passages to the peripheral compartments, means for feeding the substance to be filtered upon the filtering material on the upper side of the wheel as the latter revolves, and water-supply pipes to spray water upon said substance, substantially as described.

3. In a filtering apparatus, the combination with a revolving wheel having separate closed compartments on its periphery and provided with a circumferential covering of filtering material, of a shaft having a number of separate longitudinal passages, a series of tubular spokes placing said passages in communication with the peripheral compartments, an exhaust-pipe having one end brought into communication with a plurality of the passages in said shaft as the wheel revolves, means for feeding the substance to be filtered upon the upper side of the wheel and upon the filtering material as the wheel revolves, pipes to spray water thereon, and brushes to remove the residue of said substance after the separation is effected, substantially as described.

ASKIN MORRISON NICHOLAS.

HARRY HALE.

The Burt Rapid Cyanide Filter.

Written for the MINING AND SCIENTIFIC PRESS
By E. BURT.

At the plant of the El Oro Mining & Ry. Co., after the erection of the second 100 stamps known as Mill No. 2, it was decided to treat all the sand and slime in the new cyanide plant, where they could be handled more advantageously with the larger units.

When this change was made, and with the aid of tube-mills for fine grinding, there were produced 550 to 600 tons of slime to be handled daily. This slime is handled entirely by the decantation process, and owing to crushing with cyanide solution in the batteries, a large amount of solution per ton of slime treated has to be precipitated daily. This amount is 9 tons of solution to 1 ton of slime. Of the five washes given to the slime, the first is mill solution collected with the slime, which with the next three washes are run to the precipitation boxes, while the fifth wash is run to the mill-solution vats. With all of this washing, and the slime being discharged with only 40% moisture, there was still a difference of 10 to 15 cents gold and one to two tenths of an ounce silver between the samples of washed and unwashed slime-discharge. Aside from the loss in dissolved metal there was a small loss in cyanide.

With the idea in view of cutting down these losses, and also of treating the slime with a smaller proportion of solution per ton of slime, experiments were started to see what could be done by filter-pressing. After trying two different systems on a small scale it was decided to work out a system where gravity pressure could be utilized, and after a great amount of work and experimenting a cylinder type of press was evolved.

This press consists of a cylinder pivotally mounted or set in a fixed position at an angle of about 45°, with large door at its lower end.

- A-BURT PRESSURE FILTER.
- B-WASH WATER TANK.
- C-WASH SOLUTION TANK.
- D-FORCE PUMP.
- E-BY PASS.
- F-SLIMES SUPPLY TANK.

It carries a series of filter-mats, swingingly suspended on its interior, each mat having a connection which passes through the shell to a main solution-pipe fixed to its exterior. These mats consist of two sheets of heavy canvas enclosing a core of cocoa-matting or burlap. The edges of the canvas are lapped over and sewed so as to enclose a perforated pipe bent in the shape of an ellipse. The ends of this pipe almost meet in a special T, which is held rigid against the interior of the shell, and the perforated pipe turning in the T allows the mat to swing. The door at the lower half of the end of the cylinder is of such dimensions that the opening is equal to one-half the area of the end. It is made large to allow easy exit of the slime without the use of much water. An 18-in. valve was used on a 3-ft. cylinder, and it was found that the hard cake of slime would bank up against the shoulders and not discharge. A door of liberal dimensions allows the changing of cloths without taking off the cylinder-head. The door is opened and closed by an arrangement of toggles operated by a hydraulic or air-cylinder. The toggles work against a cross-head, which in turn is held in place by side-rods bolted to the head of the cylinder. On the bottom side of the cylinder near the door is placed the one connection for admitting slime, wash-solution, or wash-water, and for displacing any surplus slime or washes. There is a valve on the main solution-pipe on top of the press, and an air-connection to the pipe. To the top of the cylinder is fastened an air-connection. For operating the press the valves are so arranged with different connections for slime-feed by gravity from the surplus vat, or for wash-solution or water, that they can be operated by one man. To operate the press (referring to the accompanying illustration) the slime is forced in under a pressure of from 40 to 60 lb., until a cake *H* of the desired thickness is formed on the mats. Then the slime-valve is closed and the air-valve *F* and the discharge valve *M* are opened. Air at a low pressure is admitted to the shell and forces out all of the soft slime, and at the same time this pressure keeps the cakes in place. All this material flows back to the slime-supply vat. The discharge-valve is then closed and wash-water is admitted. After a sufficient length of time the wash-water is shut off and air is admitted to the shell again, until all of the excess liquid is displaced, and a large part of the moisture in the cakes is driven off. The solution-valve *D* is then closed and air at a low pressure is admitted to the pipe *B*, and through its connection to the filter-mat pipes, thus causing the cakes to drop off and slide out of the shell. Before kicking the cakes off the mats the door *O* is opened by means of the hydraulic cylinder *A*, the first and upward motion of the piston-rod draws the toggles out of position, and a continuation of this motion draws the door open sufficiently to allow the material to slide out of the shell. If the press is being operated by gravity pressure there is a small amount of surplus slime run to the vat. For the next operation this surplus slime is first pumped into the press, partially filling it, then the pump is stopped and the gravity slime-feed valve is opened and the operation carried on as before. Another method of operating is to fill the shell with slime and then shut the slime-feed valve and let in wash-solution, when all of the slime will form cakes; then the washing or treatment can be continued as long as desired. This wash-solution may be displaced with air, which gives an 'air leaching' to the slime, and then the washing may be continued again, if desired.

If a low air-pressure is maintained against the cake of slime it will not crack, but if the pressure is raised to 10 or 20 lb., or a 15-in. vacuum be maintained on a cake, it will crack. It has been found that an air-pressure of 10 lb. can be kept on a 1½-in. cake for 10 minutes, and then

by introducing a slimy wash-water the slime will immediately fill the cracks, and then the washing proceeds as usual. Using a pressure of 50 lb. it requires about ½ minute to fill the crack in the cake, and to complete the total washing 15 to 20 min. The time occupied in filling the cracks is about ½ minute when using 50-lb. pressure.

The following data give the time of the different operations and value of wash-solutions coming from the cake, also washed and unwashed sample of residue:

No. 1.		Minutes.
Operation.		
Forming cake.....		5
Displacing slime and entering wash-water.....		22
Total time		27
Cake 1½ in. thick, made at 75-lb. pressure; wash-water used per min., 60 gal. at 90-lb. pressure.		

SOLUTION ASSAYS.		Gold.	Silver.

The condition of the filter-mats can be readily told by closing the cock in the branch pipe, connecting to the solution-pipe, and opening the little pet-cock on top of the T. A battery of these presses can be operated as a single unit or separately; any one of them may be cut out to change cloths. The cloths last about six months and require acid treatment once a month. The life of the cloth may seem short, but when the following figures are

examined it will be seen that each cloth has a large capacity from using a pressure of 40 to 60 lb., thus:

Size.....	42 in. by 20 ft.
Weight, in pounds.....	12,800
Capacity, in tons of dry slime per 24 hr.	120
Number of mats.....	28
Area one side of mat, in sq. ft.....	8
Total volume of shell, in cu. ft.....	208.8
Total volume of mats, in cu. ft.....	6.3
Total volume of cake 2 in. thick, in cu. ft., moisture 28%, 110 lb. per cu. ft.....	74.6
Total amount slime to fill shell, in cu. ft., moisture 63%, 82.2 lb. per cu. ft.....	292.5
Volume of excess slime, in cu. ft.....	127.9
Volume to pump to make cake, in cu. ft., moisture 60%.....	144.0
Total volume to pump, in cu. ft.....	336.5

Operating expenses per ton of dry slime, 4 c. gold when using gravity-pressure, and 8 cents using pump.

The amount of surplus slime to be handled at each operation is 39% of the total slime run into the press.

The time of making a cake is so short that there is no settlement of the sandy portion, if there be any. After one or two operations, and measuring the cake, a definite number of minutes can be used as a criterion, so as to make the same thickness of cake. If the slime is very thick the cake will form quicker, but it will not be so compact as when made with a more dilute slime. The solution-filter is built on the same plan, except that there is no discharge-door, and the cloths are placed as close together as the connections will allow. The entire space inside the cylinder is occupied with cloths, except a few inches under the cloths to allow for sluicing out the thin cake that drops.

One of these presses, 54 in. by 17 ft., with 70 cloths, recently installed in the mill of the Mexico Mines of El Oro, has been filtering 2,400 tons of solution per day for 30 days and has only been cleaned once, and that was when a decanting-pipe was dropped, allowing slime to get into the filter.

A NEW METHOD of determining azimuth has been developed that is believed to possess certain advantages on the score of simplicity, in those cases where only a moderate degree of precision is sought. The especial merit of the method is that it requires no knowledge of the time or latitude, either for the observation or for the subsequent calculation. While a watch is used in the observation, its sole purpose is to measure an interval of a few minutes, and the watch may as well be wrong by any amount as to be right. The method involves observations on Polaris and one other star not near the pole, which for convenience may be called the 'time-star.' The distinctive feature of the method, and the only one for which any novelty can be claimed, is that the interval between the observation on the time-star and that on Polaris is made such that the hour-angle on Polaris is either the same as that of the time-star or different from it by 12 hr., but it is quite unnecessary to know what the hour-angle is. In order that the interval between observations may not be inconveniently long, the time-star selected should have a right ascension either a few minutes less than that of Polaris, or a few minutes less than that of Polaris increased by 12 hours.

AUTOMOBILES valued at more than 10 million dollars passed through the ports of the United States in its foreign trade in the fiscal year just ended. Five and a half million dollars' worth of these were exports and 4½ million dollars' worth imports. In addition to the 5½ million dollars' worth of automobiles exported to foreign countries, about \$100,000 worth went to Porto Rico, \$160,000 worth to Hawaii, and about \$5,000 worth to the Philippines. The United States occupies second rank among the commercial nations as an exporter of automobiles, being exceeded only by France.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

C. L. L., of Millers, Nev., sends Anglesite.

J. P., of Eureka, Nev., sends impure Lignitic material.

Specimens of Graphitic Schist were received from B. N. S., of Orient, Washington.

G. E. R., of Barstow, Cal., sends a specimen of massive red Garnet and green Pyroxene.

A specimen of Muscovite Schist of no value was sent by W. C. F., of Benson, Arizona.

The two minerals from Salome, Ariz., are: No. 1, lamellar Hematite; No. 2, Magnetite.

Specimens sent by W. H. S., of Lundy, Cal., are: No. 1, 2, and 3, Pyrrhotite in quartz; No. 4, Pyrite in quartz.

The specimen from W. H. B., of Valdez, Alaska, is mainly Pyrrhotite in quartz, and a small amount of Chalcocite and Molybdenite.

The rocks sent by H. N. S., from Mexico City, are: No. 1, Graphite and Pyrite; No. 2, Olivine Basalt; No. 3, Olivine Basalt; No. 4, Olivine Basalt stained with hematite; No. 5, basaltic Pumice.

R. I. G., of Fairview, Nev., sends: No. 1, Hornstone; No. 2, Syenite; No. 3, Rhyolite; No. 4, metamorphosed volcanic; No. 5, altered volcanic; No. 6, Quartz Porphyry; No. 7, Feldspar Porphyry; No. 8, altered Porphyry; No. 9, Quartz with graphitic specks.

Specimens marked S. T., from Tonopah, Nev., are: No. 1, Mica-schist; No. 2, Slate; No. 3, Green Fluorite; No. 4, Mica-schist; No. 5, Schist; No. 6, Serpentine and Tale; No. 7, Mica-schist; No. 8, Carbonaceous Schist; No. 9, Mica-schist; No. 10, Schist; No. 11, Quartz with Molybdenite; No. 12, Mica-schist.

The specimens from Mogollon, New Mexico, marked A. G. P., are: No. 1, Quartz-talc rock; No. 2, kaolinized Rhyolite; No. 3, Quartzite; No. 4, Quartzite; No. 5, Quartz; No. 6, cellular Quartz; No. 7, Quartz with Malachite; No. 8, Quartz and Wollastonite; No. 9, Quartz and Argentite; No. 10, altered Zeolite, stained by Hematite.

The specimens received from W. L. G., of Fairview, Nev., are: No. 1, Hematite; No. 2, Quartz Porphyry, stained by oxides of iron; No. 3, Quartz Porphyry; No. 4, Rhyolite; No. 5, Feldspar and Chlorite; No. 6, Quartz Biotite Dacite; No. 7, Garnet in quartz; No. 8, Quartzite with oxidized Pyrite; No. 9, Stibnite; No. 10, Garnet and Molybdenite; No. 11, Quartz with red Hematite; No. 12, Pyrite and Sphalerite in quartz.

The specimens from Manhattan, Nev., marked G. J. G., are: No. 1, Bornite in Epidote rock; No. 2, Talc Schist with Malachite; No. 3, Chloritic rock with Calcite vein; No. 4, Metamorphic rock stained by Hematite; No. 5, Quartzite; No. 6, Quartzite stained by Epidote and Iron; No. 7, Metamorphic; No. 8, decomposed rock stained by Iron Oxide; No. 9, Serpentinized rock with Malachite stains; No. 10, Chalcocite and Chrysocolla.

Electric Zinc Smelting.

By FREDERICK T. SNYDER.

*Iron, copper, and lead are smelted in bulk in single furnaces, putting through from 200 to 500 tons in each 24 hours. The reason why zinc ore cannot be smelted in an iron or lead blast-furnace is well known—the oxygen of the blast burns the reduced zinc back to oxide as fast as it is formed. In such furnaces the object, and the only object, of the blast is to furnish heat by burning the coke in the charge. If this heat be put into the stack by means of an electric current, as it is put into the filament of an incandescent light, the blast is not required and zinc as reduced will remain metal and may be condensed and removed.

Without going into the technical details of this electric stack method, I may say that these furnaces look substantially like an ordinary lead or copper water-jacketed furnace, but are provided with electrodes for carrying electricity in place of the tuyeres for carrying a blast. The ore is fed at the top and is entirely melted down, the residues being tapped as slag. The zinc condenses on the inside of the walls as spelter and runs down and is drained off. No blast is used, all the heat being put in with an electric current.

This solution, simple as it is, required an unexpected length of time to be put into a practical operative apparatus, but has now reached a form where we are warranted in considering what it means commercially to the mine owner. It is an economic truth that in the long run improvements in process accrue to the benefit of the owners of raw material. Excessive smelting profits soon attract new capital which reduces the net return to a normal interest basis. But no amount of investment can increase the grade of mineral in a deposit. To render the lower grade available for shipment a reduction must be made in the total cost of extracting and delivering the contained metal to the consumer.

For the purpose of arriving at definite figures, we can consider the result of two plants, each of 25,000 tons annual capacity, operating under equivalent traffic conditions in the Illinois coalfield, one using retorts and the other an electric stack furnace. Incidentally it may be remarked that single electric zinc furnaces of 50,000 tons annual capacity now appear practical.

The first cost of the present type of retort plant, including land, buildings, and machinery, but excluding working capital, will be some \$400,000. The equivalent first cost of the electric stack plant, including steam-driven electric generating machinery, will be substantially the same. Of this \$160,000 is the cost of the stack plant and \$240,000 the cost of the electric generating plant. Where current can be purchased from an existing power plant, the total cost of the electric stack plant is considerably less than half the cost of a retort plant. General operating cost for salaries, interest, and depreciation are substantially the same for the retort plant and the electric stack furnace.

The operating cost item of labor in a modern retort plant burning coal with mechanical roasters may be taken at \$4 per ton of raw ore. The labor in a stack plant may be kept well under \$3 per ton. While this result might naturally be expected from using one compact vertical iron-jacketed furnace in place of 2,000 horizontal clay retorts, it also depends on items not so obvious. The area of the stack plant is much smaller and distances over which material has to be handled are less and the continuous treatment admits the introduction of ore-handling machinery. With the electric stack furnace the sulphur

does not have to be roasted as low as with retorts; 6% of sulphur in the electric stack furnace will give as good an extraction of zinc as 1% sulphur with retort furnaces. This practically doubles the duty per square foot of hearth area of the roasters. The weight of the stack slag is less than one-half the weight of the retort residues and less than one-quarter of the bulk. The results of operating the electric stack furnace are to a large extent independent of the skill of the furnace-men, being determined, as in lead and copper smelting, by the metallurgist. This renders the electric stack plant, when starting up or in the event of labor troubles, much less dependent on a supply of specially skilled employees.

Considering fuel, it may be taken that a regenerative retort plant will burn 4,200 lb. of coal per ton of raw ore. Of this 600 lb. will be used in roasting. With the electric stack furnace it takes 1,200 hp. hours of electricity per ton of raw ore, or 50 hp. per day of 24 hr. The Fisk Street station of the Chicago Edison Co. is delivering one horsepower for one hour in electricity at the switchboard with the consumption of less than 1½ lb. medium grade coal. This amounts to 1,800 lb. of coal per ton of zinc ore and is practically constant whether the ore is high or low in zinc. So, aside from roasting, the electric stack plant uses one-half the coal that a retort plant uses. As roasting for stack smelting takes less than one-half the coal that roasting for retort work requires, the total coal consumption of the electric stack plant is not more than one-half that of the retort plant. The saving is substantially one ton of coal per ton of ore, amounting to 75 cents.

With the retort plant 800 lb. of reduction material will be used per ton of raw ore; with the electric stack plant 200 lb., assuming in each case a furnace charge carrying 50% zinc. With normal prices this saving amounts to 55c. per ton of raw ore.

With the electric stack plant there are no clay retorts and all cost items incident to their manufacture are absent. The items involved in the supply of new retorts amount to 40c. per ton of raw ore. With a stack plant, however, an item of expense is present which is absent in a retort plant. To smelt 25,000 tons of ore will require 100 tons of electrodes, costing \$50 per ton delivered, which is equivalent to 20c. per ton of raw ore.

Repairs and renewals on iron work and machinery will be substantially the same in each plant.

Summing up these differences of operating costs, it appears that the electric stack plant costs \$2.50 less per ton of raw ore to operate than the retort plant.

SALE OF COPPER.—Within the past year or 15 months there has been a number of changes effected in the agencies through which some of the leading copper producers of this country dispose of their metal. The most important of these are the transfer of the Baltic output now included in Copper Range from the American Metal company to the United Metals Selling company, the shifting of W. A. Clark's Montana product from the Vogelstein agency to the American Metal company, and the acquisition of the Bingham Consolidated output by the Vogelsteins from the United Metals company. The product of the United Verde, formerly handled by L. Vogelstein & Co., is now sold by W. A. Clark through his manufacturing concern in New Jersey, the Wacark Wire company. While the American Smelting & Refining Co. sells about 60,000 lb. through the United Metals company, the Guggenheims sell annually through the American Smelting Securities Co. approximately 30,000,000 lb. This includes the output of the Tacoma Copper company, formerly sold through L. Vogelstein & Co.—*Boston News Bureau.*

*Abstracted from *Transactions of the Tristate Mining Association.*

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

CONVERTER.—No. 870,925; Ralph Baggaley, Pittsburg, Pennsylvania.

A copper converter composed of a refractory lining, heavy metal blocks forming the exterior walls, and a water-cooled tuyere block inset into the metal blocks and against the outer surface of said lining adjacent to and around the tuyere orifice; substantially as described.

MINING SULPHUR.—No. 870,620; Herman Frasch, New York, N. Y., assignor to The Frasch Sulphur Process Company, Kittery, Me., a Corporation of Maine.

The improved process of fusion mining in porous deposits, which process is characterized not only by the introduction of fusion fluid into an underground porous deposit of fusible material and by the removal of the melted material therefrom, but also by the introduction of comminuted material into said deposit in order thereby to restrict the freedom of movement of said fusion fluid in the deposit, substantially as described.

MINER'S CANDLESTICK.—No. 870,638; Guy D. Neill, Denver, Colorado.

In a miner's candlestick, the combination of an expandible yoke having normally parallel, longitudinally grooved jaws, and a pair of pivotally connected supporting devices,

pivotally positioned within the grooves, the said yoke being adapted to pinchingly retain the said devices in their adjusted positions.

AMALGAMATOR.—No. 870,643; George E. Paullins, Colorado Springs, Colorado.

The improved apparatus for the purpose specified comprising a wooden trough having its rounded bottom lined with copper, and provided with a series of transverse partitions, alternate ones extending to the bottom and terminating below the top of the trough, and others terminating above the bottom of the trough and extending to the top thereof, a shaft passing through the longitudinal centre of the trough, a series of agitators keyed thereon, and comprising radial arms and strips connecting their outer ends, an endless conveyor arranged in the last compartment which is adjacent to the last of the series of agitators, a perforated pipe arranged along one side of the trough for delivering mercury into the several compartments containing the agitators, a pipe arranged for discharging a saline solution into the trough, and electric-circuit connections comprising conductors extending to a source of electric supply, one of said conductors being connected with the copper lining of the trough, and the other with plates arranged in the trough, as shown and described.

MINER'S PICK.—No. 871,058; William Donaldson and Elmer E. Donaldson, Moingona, Iowa.

A miner's pick, comprising a head having a handle socket formed on its under side, and having a transverse slot through its central portion, and two tapered openings extended from the ends of the head toward said transverse slot, and flattened openings extending from the tapered openings to the interior of the transverse slot, and two detachable pick points, each having a round tapered end portion with a flattened portion at the inner end of each tapered end portion, said pick points inserted in the tapered openings with the flattened portions thereof projected through the flattened openings and into the transverse slot, said head shaped to protect the adjacent ends of the pick points and to completely cover them, said pick points being so arranged within the head that they may be jointly driven from the head by a wedge passed through the transverse slot.

Books Received.

The Canadian Mining Journal issues a handsome volume commemorating the visit of the American Institute of Mining Engineers to Cobalt and Sudbury. A large number of excellent illustrations and some neat maps give additional value to the publication. Price, post-paid, \$1.

'Principles of Reinforced Concrete Construction,' by F. E. Turneaure, Dean of the College of Engineering, and E. R. Mauser, Professor of Mechanics, University of Wisconsin. Published by John Wiley & Sons. 8 vo., viii + 317 pp., 11 plates, 130 figures. Price \$3. In this, the latest book on this subject, a full treatment is given of the principles of mechanics underlying the design of reinforced concrete, together with the results of all available tests made in attempts to determine coefficients and working stresses; it also describes and gives detailed drawings of the latest forms of reinforcement of concrete. For sale by the MINING AND SCIENTIFIC PRESS.

'A Manual of Fire Assaying.' By Charles H. Fulton, President of the South Dakota School of Mines. 8vo. 178 pp. Published by the Hill Publishing Co., New York. This makes another of the many treatises on this subject; but this is one of the best, for it has been prepared by an experienced assayer and teacher. The book is confined closely to the subject of fire-assaying and treats of it in great detail. The chapters on 'Reduction and Oxidation Reactions,' 'Crucible Assay and Assay Slags,' and 'Cupellation' are especially good. It is an excellent manual for students and a useful book of reference for assayers. The book is well illustrated. For sale by the MINING AND SCIENTIFIC PRESS at \$2.

'Electro-Analysis,' by Edgar F. Smith, Professor of Chemistry, University of Pennsylvania. Fourth Edition, 1907. Published by P. Blakiston's Son & Co. 336 pp. Price \$2.50. The rapid advance in the technical applications of electro-chemistry has caused the publication of a fourth edition of this book. Not only the older time-honored methods of electro-analysis are given in detail but also the latest methods, which laboratory research has proved to be accurate. Especial attention has been paid to describing the rapid methods of analysis depending upon the use of a mercury cathode and rotating anode. The length of time consumed in each precipitation is given, which greatly increases the usefulness of the book. It also contains a section upon the determination of cations and anions. For sale by the MINING AND SCIENTIFIC PRESS.

Publications Received.

From Cornell University, Ithaca, New York, we have received 'The President's Report' for 1906-1907.

The Illinois Bureau of Labor Statistics has sent us its 'Twenty-fifth Annual Coal Report,' giving the statistics of the coal industry of that State for 1906.

We are in receipt of the following advance chapters from the 'Mineral Resources of the United States for 1906': 'The Production of Graphite,' by George Otis Smith; 'The Production of Coal,' by Edward W. Parker.

U. S. GEOLOGICAL SURVEY.—Advance chapter of the 'Mineral Resources of the United States' for the Year 1906: 'The Production of Lime and Sandlime Brick' by Edwin C. Eckel. Also Bulletin No. 309, 'The Santa Clara Valley, Puente Hills, and Los Angeles Oil Districts, Southern California,' by George Homans Eldredge and Ralph Arnold, 266 pages.

We have received the following advance chapters of the 'Mineral Resources of the United States' for 1906: 'The Production of Platinum,' by David T. Day; 'The Production of Mineral Paints,' by Edwin C. Eckel; 'Summary of the Mineral Production of the United States,' by Wm. Taylor Thorn; 'The Manufacture of Coke,' by Edward K. Parker; 'The Production of Antimony, Arsenic, Bismuth, and Selenium,' by Frank L. Hess; 'Statistics of the Clay-Working Industries in the United States,' by Jefferson Middleton; 'The Production of Manganese Ores,' by Edwin C. Eckel.

Commercial Paragraphs.

WM. P. BARBA, superintendent of the steel foundry of the MIDVALE STEEL CO., at Philadelphia, accompanied by JAS. C. H. FERGUSON, their Pacific Coast representative, are making an extended tour in the West to visit the smelters of Montana, Utah, Arizona, and Mexico.

J. H. ELSPASS, president of the Elspass Engineering Co., Denver, recently closed a contract with the U. S. Government for an Elspass mill, Pierce amalgamator, and other machinery for use in the mint at San Francisco. This is the second plant of the kind this company has sold to the Government for use in a mint, the other one being at Denver.

THE DENVER ENGINEERING WORKS CO. does not keep completed gears in stock, as we stated recently, but instead carries a large line of patterns for both machine cut and cast gears; this enables them to furnish gears on short notice. The rigid rolls, made by them, are so constructed that, when a large piece of iron or steel, such as a hammer-head or broken drill, gets into the rolls, a simple shearing-pin, consisting of an ordinary bolt, will break, thus preventing injury to the roll faces.

THE WELLMAN-SEEVER-MORGAN CO. has just opened a branch of its Pacific Coast office at 215 N. Centre St., Reno, Nevada, with L. F. White and L. L. Edwards as local representatives. W. Q. Wright, the Pacific Coast manager for the company, recently made an extensive automobile trip, visiting all the important Nevada camps, and has not seen fit to make any change in his original plans on account of the present depression. The Wellman-Seever-Morgan Co. manufactures a complete line of mining and power machinery. Their engineering department is prepared to design complete equipments for mines and metallurgical plants. The Reno office will make a special study of Nevada conditions and will be in a position to give their clients the benefit of a large and experienced organization. Associated with the Nevada office, a construction company has been organized for the purpose of taking contracts for the installation of mining and reduction machinery, and for the construction of complete plants, turning these over in running order and taking all risks connected with the construction.

Catalogues Received.

THE C. O. BARTLETT & SNOW CO. of Cleveland, Ohio, have issued 'General Catalogue No. 18' for 1908.

THE CYCLONE DRILL CO., of Orrville, Ohio, has issued an attractive little booklet illustrating their drilling outfits.

THE JOHN A. TRAYLOR MACHINERY CO., of Denver, Colo., has issued bulletin 'H,' describing their line of crushing machinery.

THE WESTERN ELECTRIC CO. of San Francisco has issued a beautifully illustrated catalogue entitled 'Poles,' describing the way of handling timber used in the poles, piling, and railroad ties, sold by that company.

THE A. LIETZ CO. of San Francisco, have issued 'Publication C,' illustrating drawing instruments and office supplies such as are used by architects and engineers. 'Publication A,' illustrating the surveying instruments manufactured by that company, will soon be ready for distribution.

THE WESTERN METALLURGICAL CO. of Denver has issued a booklet entitled 'Mineralogist's Pocket Reference,' in which is given useful mineral tables and condensed information about the principal ores. It also gives prices charged by this company for analyzing and testing different substances.

THE THOMPSON BALANCE CO. of Denver has recently issued a 32-page catalogue entitled 'Precision Balances and Weights.' The catalogue describes the different styles of balances manufactured by this company, and especially their multiple rider attachment. In this attachment riders take the place of all flat weights for weighing up to 72 mg. on button-balances and up to 720 mg. on analytical balances.

Editorial.

FAULTING of veins presents many problems of practical moment to the miner. Therefore, careful descriptions of such occurrences are always welcome. In this issue Mr. H. W. Turner, a geologist and mining engineer well versed in such matters, gives a valuable article on the conditions observed in the Red Cloud mine.

FURTHER LETTERS discussing professional customs appear in this issue. We have a few more and they will appear shortly. Then we hope to summarize the discussion, which has proved interesting and, we hope, useful. In the meanwhile someone may wish to ask some really difficult questions in regard to professional ethics. They will be welcome.

EXPORTS OF COPPER during November were the highest on record, namely, 33,787 tons, as compared to 18,451 in the corresponding month of last year, and 13,195 tons two years ago. During the first eleven months of 1907 the exports totaled 189,167 tons, as compared to 190,615 tons during the same period last year. The sudden increase in the export of the metal explains the recent recovery in price, which was not maintained.

NEVADA has no State Militia, hence the Governor had no citizen troops at his disposal and called upon the Federal authorities for the protection deemed necessary at Goldfield. This obviated an intermediate condition of pseudo-military rule, usually prejudicial to the solution of industrial disturbances. Citizen soldiers do excellent work against a foreign foe, but as a weapon for quelling domestic disturbances they are unsatisfactory, simply because the military instinct is subordinated to political and economic prejudices.

IT IS INTERESTING to note that an intelligent foreigner landing at New York, and examining the new \$10 gold-piece, remarked that the pantalated eagle closely resembled that upon an old Roman coin, and, on noting the absence of the motto, "In God we trust", this same foreigner voiced his regret that the four words which had expressed Lincoln's unshaken faith in the future of America should have been dropped. If we are to come to a purely agnostic basis, then the Thanksgiving proclamations are mere solecisms and we might as well be frank about it, inscribing upon our coins the battle-cry of a blatant materialism: "In Gold we trust."

SOME NEW FEATURES of feline finance are being illustrated in the case of the Llanos de Oro company, which was organized to exploit "plains of gold" in Sonora, Mexico. One of the interesting facts is that \$445,000 was plumped into a mining venture without engineering advice and the money was then expended

under the direction of an architect. Litigation is now pending between the promoters and it is likely that further illumination of the by-ways of speculation will be forthcoming. The pity of it is that such exposures come at the end of a boom, when wild-cats run to cover, and not at the beginning of a period of excitement, when a few object lessons might deter the simple from throwing away their money.

EXPERIMENTS are being made in a systematic way at the University of California to determine the flow of sand in rivers. These experiments are being conducted by the United States Geological Survey under the supervision of that veteran geologist, Mr. G. K. Gilbert. This is a part of the efforts made to solve that interminable tangle called the debris problem. It is hoped to find out how to maintain navigable conditions in the larger rivers receiving the drainage of the Sierra Nevada, not to mention the tailing from the gravel mines, of which class of material but little now finds itself into the rivers—for a good reason, most of the mines having been stopped by litigation and blackmail.

Conditions at Goldfield.

IN NOVEMBER the mine operators at Goldfield, by reason of the impossibility of obtaining currency, announced that they would pay wages in scrip. Thereupon the local miners' union, which is affiliated with the Western Federation of Miners, declared a strike. On December 2 the association of operators announced an abrogation of all agreements existing with the miners' union. Two days later the President issued orders for Federal troops to be in readiness to go to Goldfield, this action at Washington being due to representations telegraphed by the Governor of Nevada, in which he informed the President that the local authorities were unable to protect the community from disorder. On December 5 the general in command in California sent 435 men, in two detachments, to Goldfield and they reached that town on the 8th. Then the operators announced a decrease in wages, miners to be paid \$4, in place of \$5, per day and ordinary laborers \$3.75, instead of \$5, the rate hitherto prevailing. At the same time it was stated that an effort would be made to reduce the abnormal cost of living in the district and if the local merchants did not reduce prices, the operators would establish stores to remedy the excessive cost of food and supplies. On December 9 notice was given that three days later the operators would try to resume mining operations, employing all such men as accepted the new scale of wages, provided they were no longer members of the Western Federation. It is understood that a number of men are to be imported from California to take the place of those refusing to return to work under the conditions imposed by the operators. On December 11 the President ordered three representatives of the Department of Commerce and Labor to proceed from Washington to Goldfield, to ascertain the real conditions prevailing in Nevada, with a view to a trustworthy report. To complete this record of events it should be

added that on December 9 the Western Federation officially terminated or "called off" the strike in the Cripple Creek district. This strike, which led to numerous outrages both by miners and operators, was declared in August, 1903.

Beyond the facts narrated in the preceding paragraph it must be stated that the present crisis at Goldfield is the inevitable climax of conditions that have disgraced Nevada and the United States for two or three years. The agitators responsible for the troubles in Colorado and Idaho have congregated to the new bonanza camps of Nevada and they have established a terrorism concerning which comparatively little has been printed, mainly because the mine operators deprecated the publication of information likely to affect the speculation in stocks. At least a score of men have been killed or have disappeared in a suggestive way during the past two years, many more have been assaulted, beaten, and driven out of the district by ruffians claiming to act in the interest of the miners' union, and a number of mining engineers and operators from Colorado and Idaho have been warned not to come to Goldfield. Most of them have heeded the warning, otherwise additional brutalities might have occurred. This industrial devil's kettle has been simmering for a long time and if it did not boil over before the eyes of the world, it was because the greed of men caused them to endure tyranny rather than induce an exposure that would have killed the gambling in mining stocks. Now that the monetary flurry has put a temporary end to flamboyant finance and the stock market looks less important than the real work of mining, the operators have forced the situation and unmasked the anarchy that has prevailed so long. The lessees, who have operated most of the rich mines until lately, paid preposterous wages, as compared to other districts, because they were in a hurry to extract ore of unusual richness; the miners knew that the operators' anxiety to avoid a cessation of work gave them the whip hand and so they made excessive demands, until Goldfield upset the whole labor market of the West. It was an unstable state of affairs and was bound to come to an end. That end is now in sight.

The sending of Federal troops is much to be commended. They are there, as the President says, "neither for nor against the strikers or the employers. They are to prevent riot, violence, and disorder, under and in accordance with the Constitution and the laws of the land. No man is to be interfered with as long as he conducts himself in a peaceful and orderly manner." In face of the failure of the local authorities and of the State to enforce the law and to ensure each man protection while at work, there was nothing else to do and we deem it fortunate that the troops were sent so promptly. The Federal investigation of the local industrial conditions is also likely to be useful. Publicity will help to curb the actions of both sides and it is right that the country should be informed of the real facts of the case, so that public opinion may be rendered intelligent and effective. The newspapers, unfortunately, take sides in these industrial quarrels, so that the

average man rarely gets anything but a distorted story. Let there be a fair field and no favor. If a man does not care to work for \$4 per day, he has the right to refuse; if another man is willing to take \$4 per day, he ought to be able to go to work unmolested, even if it takes the whole United States Army to protect him from violence. On the other hand, the operators have no right to ask a man to what union, club, or political party he may belong, and while in this case the Western Federation is justly treated as an outlaw, we regret that the operators should discriminate against men by reason of their affiliations. We hope the quarrel will be fought to a conclusion without any of the violence and brutality that marked events in Colorado and Idaho. The country is deeply interested in seeing that this purely industrial dispute is settled lawfully. The success of either disputant is wholly secondary to the maintenance of representative government.

The Late Unpleasantness.

IT IS SAID that the panic of 1873 most nearly compares with that of 1907. The Civil War in America, the wars of Italy and Prussia against Austria in 1866, and the Franco-German war of 1870, had destroyed a vast amount of capital. The United States had escaped the forced liquidation following upon the collapse of credit in Europe and had absorbed an enormous amount of capital in the reproductive enterprises started after the Civil War. Railroads had been built at a tremendous rate, joint-stock companies and mining schemes had permitted of reckless inflation, so that by 1873 everything was ready for the explosion started by the failure of Jay Cook & Company. On the other hand, in 1898 we had the Spanish-American embroglio, in 1899 and the succeeding three years the Boer war, in 1904 the tremendous struggle between Japan and Russia; then came the destructive earthquakes of San Francisco, Valparaiso, and Kingston, each accompanied by direct and indirect destruction of capital, reaching in the case of the San Francisco seismic conflagration to no less a sum than \$500,000,000. Despite the waste of productive energy and the obliteration of capital that occurred in rapid succession during the eight years, from 1898 to 1906, the United States enjoyed an almost uninterrupted industrial development and a business boom of magnificent proportions. The reaction was bound to come; it came; it is passing.

At least \$25,000,000 of emergency currency was in use a couple of weeks ago in the various cities of the country outside of New York. These makeshifts are really prohibited by law, for the National Bank Act recites that "no national banking association shall issue any other notes to circulate as money than such as are authorized by the provisions of this title." It would be well to amend the law in this matter in accord with public usage, for infractions of law, even if generally approved by public opinion, are detrimental to good government. It is estimated that the total amount of emergency currency issued in 1907 was at least four times that in circu-

lation during the panic of 1893. However, a statement was made in Congress that not a dollar was lost by anyone accepting such notes in 1893, even when they were tokens printed and circulated by merchants. They were retired immediately upon the resumption of cash payments by the banks, and it is likely that those of 1907 will enjoy an equally brief but useful career. Hoarding by anti-social individuals has been succeeded by hoarding on the part of nervous bankers. At New York the panic was short-lived; it has been followed by extreme efforts at self-preservation by interior banks that have heaped up reserves to meet an expected crisis. Then London became scared and our own Government made an issue of bonds that proved unnecessary. These fits of feverish anxiety are over and the good sense of the people of the country has restored confidence. Never was there a severer test of the self-reliant quality that has meant so much to American progress. At times boastful and reckless, too self-assertive, it may be, and regardless of precedent, nevertheless, the recent episode does honor to the stability of American institutions and the essential sanity of our people.

The amount of gold imported to relieve the stringency was just about equal to the annual yield of American mines—a little under \$100,000,000. Nevertheless, the withdrawal of it from Europe was likened to a raid and it caused money rates to soar. In the modern world the ratio of business done to the money changing hands increases with the growth of credit, so that nowadays only about 5% of business is done on a currency basis. The pyramid is upside down and as the actual base becomes smaller, a slight shifting produces far reaching disturbances. Such disturbances overwhelm enterprises leaning heavily on credit and disorganize business, but they become less injurious as civilization progresses and the machinery of commerce is developed. Twenty years ago such a collapse in the stock market as was seen at New York at the end of October would have been followed promptly by the announcement of many failures among brokers and jobbers, and scores of speculators would have been declared bankrupt. But nowadays there is every effort made to assist those in distress and to patch up financial holes, not entirely from altruistic motives, but because financiers realize that it is to their interest to prevent disorganization from spreading too far, until it undermines even perfectly solvent enterprises.

Various prognostications have been made as regards the course of business in the near future. The balance of probabilities indicates that the worst effects of the shock to credit will soon be over and that a slow recovery will supervene; in the spring there will be a marked revival and it will be checked only by the Presidential election. Should the result be obvious and satisfactory, it will be discounted and further expansion of business will follow. In any case, at the end of twelve months the tide of prosperity will be again in full motion. This may seem optimistic, but it is an optimism based on an appreciation of the resilient strength of a continental country in process of rapid and profitable industrial development.

By the Way.

At a recent meeting of the American Institute of Mining Engineers, Mr. James Douglas spoke concerning 'Secrecy in the Arts.' He said:

If it is the fact that technical science has progressed of late with such unwonted speed through the co-operation of many workers, and that this co-operation has been made possible by the publication and exchange of ideas and experiences in the technical and scientific journals, would not our progress be even more rapid and thorough if all barriers of secrecy were broken down, and every encouragement were given to our technical workers to describe, in print and by conference, their notions and their actual experiments? This is the attitude of some, I may almost say of most, of our large concerns, but unfortunately it is not that of all. It is impossible to compare, as to efficiency and profit, works, the gates of which are fast shut, and in which obscurity and secrecy are imposed and practised, with those to which free admission is granted and in which freedom of information is encouraged. But the following reflections force themselves upon us in this connection. We know that very few technical papers issue from certain establishments; that on their officials silence is imposed; and that to these works inquisitive visitors are politely but peremptorily refused admission. There are not many such, but they are and have been very successful. But suppose that in imitation of their practice and regulations all were tempted to adopt it, so that the same policy became universal; what a sudden paralysis of industry would follow! Our secretaries would find it difficult to fill even their shrunken volumes of transactions with papers worth printing; our students would have to content themselves with the antiquated learning which their professors could supply; for there would be no more summer classes for practical work in mines, smelters, and electrical factories, and the professors themselves would have to learn from old books. Every manufacturer and smelter would be obliged to bribe his neighbor's workmen and tempt away his neighbor's superintendents for information. As a result, before long, the very works which now find it so profitable, or think they do, to tap their friend's stock of knowledge and experience, and give nothing in return, would be driven in upon their own resources, and would undoubtedly then find them not so complete as they imagine. Of course, I am supposing an impossibility, because the spirit of intellectual freedom in our professions is too strong and too widespread to submit to such a tyranny, and because, before such darkness of ignorance had settled down to our great industries, the most pronounced advocates of secrecy would feel and acknowledge the ultimate consequences of concealment, and would become reformers. Today they may have secrets, as valuable as Sir Henry's method of making plate glass and bronze powder, which it may pay them to conceal from their competitors, so long as they are admitted freely to their competitor's open shops; but even this is doubtful. For the spirit of secrecy is intimately allied with the spirit of suspicion and distrust; and the mind which is always suspecting is closed tight against the admission of fresh and fair impressions. Being jealous of others, it is prejudiced against their suggestions, and correspondingly prejudiced in favor of its own preconceptions. Progress therefore ceases.

This is a temper of mind foreign to a new country like ours, whose special industries have not been established long enough to wear grooves of rigid practice and sink into ruts of self-satisfied indifference. About the best correction we can apply to the growth of dry-rot is the banishment of secrecy. A curious instance of its blight-

ing influence is seen in some of the older, not the newer, industries of the old world. The iron and steel works of Europe have not kept pace with ours in size and production, but the iron-masters of Great Britain and Germany, in coke-making and in blast-furnace economies and in steel-making processes, have been our teachers. Nor have they been shy of communicating their improvements, or, through jealousy of our success, slow in adopting ours. No nobler monument of international comity in thought and experience exists than the seventy volumes of the *Proceedings of the Iron and Steel Institute*. And with few exceptions the iron and steel works of England, Scotland, Germany, and France are open to any accredited worker in the same domain. Yet before England was conspicuous as a maker of iron, she was famous the world over for her copper and tin production. But, between self-conceit and the inbred habits of trade-secrecy, her copper-smelting industry has fallen from its high estate. And it is not accidental, but linked as closely as any effect with its cause, that this decline is in great part the result of habits of secrecy which grew with the growth of age. At Swansea, every gate to the smelting works is guarded, and as a result it has been as difficult for thought to escape out as for suggestions to find their way in. Swansea should still enjoy the leadership which her skilled labor, splendid coal, and commanding maritime situation put within her reach; but she has preferred to gloat over her secrets behind closed doors rather than go out into the world in search of new business as well as technical methods, while also inviting the world to enter and exchange ideas with her. What is the consequence? New Zealand copper comes here to be refined, notwithstanding the first practical application of electrolysis to metals was made by Elkinton in England, and the Vivians adopted the Manhes method before Farrel introduced it into this country.

There are, however, of course, exceptions in England to this too prevalent habit of secrecy. To the works of the Rio Tinto at Port Talbot or of the Cape Copper Co. at Briton Ferry in South Wales, where metallurgical novelties have been tried, introductions are not refused. But the alliance of decay and suspicion in the instance I have given can hardly be accidental; and we may be sure that what is baneful in its effects in Europe is not likely to be beneficial here; for while the Atlantic separates continents it does not delimit the operation of laws.

In political life, vitality is maintained only when every man takes his full share as a debater in the discussion of political questions, and as a voter in the determination of state affairs. So in scientific and technical matters, the banishment of deceit, mystery, and jealousy, and the freest admission of daylight by means of the unreserved diffusion of information through the press and personal intercourse, will instill into the whole body of workers a feeling of healthy rivalry, which, while stimulating their mental activity, will correspondingly benefit the financial interests of their employers.

I have supposed an extreme case—that the example set by our few secretive establishments were followed by all. Let me imagine a more probable issue, such as, I believe, will result from the fellowship of knowledge and experience which our national engineering societies have in view—namely, that all our technical manufacturers will learn how they gain, and not lose, by encouraging their staff officers to study their neighbors' methods, and by throwing open their own establishments, in turn, to the freest criticisms of their competitors in trade. What will result? Nothing but advantage, I believe, to all whose wisdom and means have enabled them to provide themselves with the raw material of manufacture on advantageous terms, and to locate their works or factories at localities favorable for economical operation.

Personal.

BERNARD MACDONALD is again at Guanajuato.

ALFRED JAMES returned to England on the *Celtic*.

VICTOR G. HILLS of Denver is examining mines in Arizona.

NORMAN ROWE has been appointed Consul at Guanajuato.

J. M. NICOL has returned to San Francisco from Nicaragua.

R. A. F. PENROSE has returned to Philadelphia from Brazil.

EDWARD D. McDERMOTT was married on November 28 at London.

F. M. SIMPSON is metallurgist at the Vivian mine, in Arizona.

F. L. BENSISAN is engineer at the Dolores mine, in Chihuahua, Mexico.

W. H. STAYER is resident manager of the Zaruma gold mines in Ecuador.

JULES LABARTHE is manager of the Trail smelter, in British Columbia.

JOHN A. CHURCH passed through San Francisco on his return from Japan.

FRED. N. ROGERS, formerly in Gilpin county, Colorado, is in San Francisco.

ARNOLD BECKER is now engaged in geological investigations at Goldfield.

C. E. RHODES, formerly at the Dos Estrellas mine, El Oro, is now at Guanajuato.

LOUIS KATONA, a Hungarian mining engineer, sailed on the *Alameda* for Melbourne.

CHARLES H. HUMPHREYS is metallurgist at the Mt. Morgan mine, in Queensland.

JESSE J. MACDONALD is now at Denver, with an office in the Commonwealth Building.

P. E. O. CARR has been appointed general manager for the Mazapil Copper Co., in Zacatecos, Mexico.

JOHN HAYS HAMMOND was in San Francisco, on his way to the gold dredging operations on the Yuba.

C. W. P. WHITE is superintendent of mines at St. Eugene, B. C., for the Consolidated Company.

EDWARD THORNTON is superintendent of the Dolores mine, near Matchuala, in San Louis Potosi, Mexico.

WILLIAM THOMPSON, manager for the Waterson Gold Mining Co., at Ocampo, Mexico, has gone to London.

NATHAN P. MANSFIELD, at one time superintendent of the Smuggler-Union mine, near Telluride, is now living at Berkeley.

THE ENGINEERS SOCIETY OF SOUTH WESTERN MISSOURI is a flourishing organization at Joplin, Mo. It has about 50 members and the following are its present officers: NAT PAIGE, president; A. E. BENDELARI, vice-president; C. S. BANKARD, secretary. Club rooms have been fitted up in the Olivia Apartment Bldg., and visiting engineers and mining men are welcome there. During the Mining Congress held in Joplin this society entertained the visitors at a smoker.

Obituary.

W. R. BOGGS JR. was killed near Topia, in Mexico, on December 1. Owing to the failure of his company to pay the wages due to the employees, a mob of miners met him on the road and stoned him to death. He was born in 1857 and graduated from the Virginia Polytechnic Institute in 1877, taking a supplementary course at Columbia. His professional work took him to Leadville and Rico, in Colorado, and to many parts of Mexico. He was an engineer of reputation and the writer of several papers on mining geology. A number of men implicated in the horrible fatality have been arrested.

General Mining News.

ALASKA.

There is quite a rush to the new gold district on Valdez creek, a tributary of Shushitna river; this camp is 200 miles from Valdez. About 300 men have left Fairbanks and about 100 have started from Valdez. This is the first important discovery in the Shushitna valley. This winter the main line of travel will be by the Valdez-Fairbanks trail rather than via Seward. Pete Monahan is stated to be the discoverer of the new district.—It is reported that much volcanic ash has fallen in the vicinity of Nome. This will interfere with early winter travel.—Gold dust and gold bricks valued at \$1,200,000 are being sent out over the snow from Fairbanks.—It is reported that Cleary city, near Fairbanks, was burned about the middle of November. The loss is about \$250,000.—The Alaska Treadwell Co., on Douglas island, is building 33 new houses for its employees. It is reported that the company can give employment to 300 more men than it has at present. The company is desirous of getting men with families.—Copper has been discovered on Nabesna creek, near the head of Copper river. A vein, 8 ft. wide, carrying chalcopryite and bornite, has been found.

KLONDIKE, CANADA.

It is reported that there is some good placer ground on Pelly river.—A. J. Beaudette, Government mining engineer, is collecting specimens of placer tin for the Canadian Geological Survey. Some placer tin occurs in the placer gravel of the Yukon river. It is claimed that tin-bearing veins have been found near the mouth of Bonanza creek and also on Boucher creek, a tributary of Sixty-Mile.—Considerable placer prospecting is being done on new creeks, flowing into the Yukon below Gibbon. At Gold Hill, about 25 miles below Gibbon, much work is being done. The town consists of 7 buildings and 150 tents. The gravel is said to prospect 45c. per pan. On Sellinger creek, also below Gibbon, 35 men are working. On Melozzi river, which flows into the Yukon about half-way between Tanana and Innoko rivers, considerable prospecting is being done. Some placer ground and some quartz veins have been discovered. It is rumored that rich gravel has been discovered on the Yukon just opposite the mouth of Melozzi river.

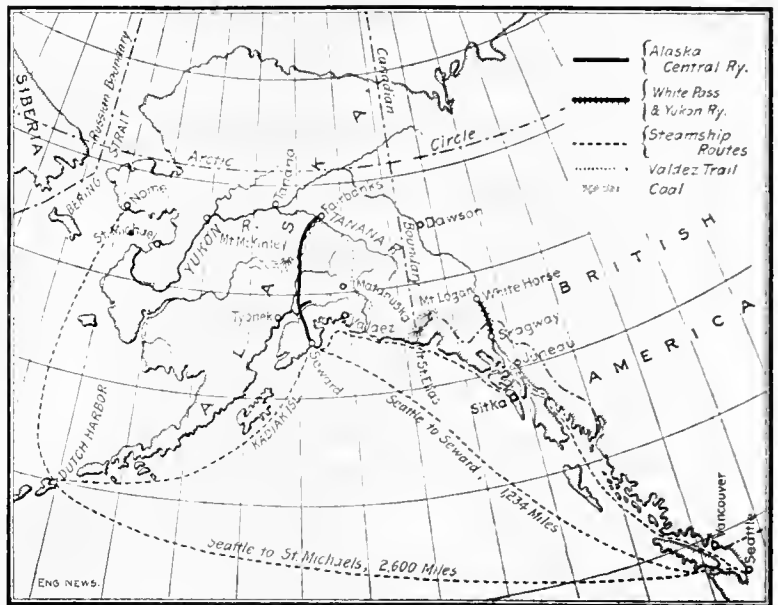

W. J. Elmendorf states that at the property of the Arctic Cliff Copper M. Co., in the White Horse district, considerable development was done last summer, and large bodies of copper were discovered. In the Arctic Cliff claims alone there are now blocked out 100,000 tons of ore. This carries from 5 to 6% copper, and from \$4 to \$5 in silver and gold per ton. The entire ore deposits of the district are of the same quality. Much development work has also been done by other companies operating in that district. Most of the development done by the Arctic Cliff company has been on the Best Chance, near White Horse. The White Pass & Yukon railway is now building a spur 12 miles in length to penetrate this district. This will also open up the Pueblo mine, which Byron N. White of Spokane has been developing for the last two years. The railway is expected to reach the mines by next July, and then shipping will begin. By that time there will be 300 tons of ore daily for shipment. This will be treated at the various smelters on the Pacific Coast. The Arctic Cliff company expects to ship about 100 tons per day.

ARIZONA.

COCHISE COUNTY.

The Copper Belle M. Co., of Gleeson, has been made defendant in a suit for \$265,416 just filed by Paine, Webber & Co., of Boston. The mine belonging to the company has produced nearly \$1,000,000 in copper. Recently the Shan-

non Copper Co. took a bond on the property for a large sum. Martin Costello also holds a mortgage for \$80,000 on the property.—The miners and shovelers at the Butte & Arizona mine refused to accept the reduction of the wages to the scale prevailing in Butte and Bisbee. Only 12 men quit, as the machinists and surface-men accepted the reduction. While labor was scarce the company paid 25 cents above the Bisbee scale. Miners have been obtained in Bisbee to take the places of those that quit. The mine is looking well and work will be continued in spite of the financial depression.—The recent strike of good copper ore in the Emerald mine, at Tombstone, continues to look well as development progresses.—The Copper Queen Co. is sinking a new shaft, called the Uncle Sam, within a short distance of the old Uncle Sam shaft and about 600 ft. west of the Shattuck-Arizona; this shaft is now 50 ft. deep. It is being sunk to develop orebodies thought to exist in that vicinity; this ground is too far from the Cuprite to be conveniently developed from that shaft. An engine and head-frame has been placed at this shaft. The three drifts which are being driven from the other properties to the Sacramento shaft are progressing rapidly. The Sacramento shaft is now over 1,100

Map of Alaska.

ft. deep and will be continued to 1,200.—The directors of the Calumet & Arizona Co. have declared a dividend of \$1.50 per share; this amounts to \$300,000 and brings the total dividends disbursed to \$9,300,000, all in five years.—At the Superior & Pittsburg shafts development work is progressing with favorable results; a new orebody has been found in L. S. & P. ground. The water pumped at the Briggs shaft is rapidly decreasing in amount; formerly 3,000 gal. per minute were raised, but now only 700 gal. This is due to the fact that the cross-cut from the Junction shaft is draining much of the ground formerly drained by the Briggs shaft. Shipments to the C. & A. smelter, at Douglas, are being made from the Hoatson, Junction, and Cole shafts.—At the Shattuck-Arizona 30 men are working; they are developing new ground on the 700 and 800-ft. levels. The damage to the shaft and the pump-station on the 800-ft. level has been repaired.—At the Denn-Arizona 10 men are working. Diamond-drilling on the 1,100-ft. level has been resumed.—The gases from the fire which hampered mining at the Irish Mag, Gardiner, and Spray shafts has been entirely controlled by the bulkheads erected.—Much repairing and overhauling is being done at the Copper Queen and C. & A. smelters at Douglas.

GILA COUNTY.

The cross-cut on the sixteenth level of the Old Dominion mine has broken into sulphide vein No. 1. The ore resembles that on the fourteenth level from the same vein; next to the hanging wall it shows a low-grade concentrating ore. At the smelter four furnaces are now in operation.—The Superior & Boston M. Co. has re-elected the old board of

directors.—At the Mallory shaft of the Globe Consolidated Co. work was suspended for 10 days until an extension could be obtained for the final payment. Work has been resumed on the 860-ft. level.

GRAHAM COUNTY.

The Shannon Copper Co. and the Arizona Copper Co. have discharged all their mechanics, owing to the refusal to accept the reduction in wages.—At the property of the New York-Arizona Gold & Copper Co. the Lillian adit is 500 ft. long; it has developed considerable ore carrying gold, silver, and copper. The Williams adit is 200 ft. long; the vein in this adit is 12 ft. wide and carries considerable gold and silver. The Thompson adit is 210 ft. long. The rich ore found on the Buzzard Shadow claim still looks well.

One of the sessions of the Grand Lodge of Masons was held in one of the stopes of the Lone Star mine of the Detroit Copper Co. This stope is 100 ft. long, 35 ft. wide, and about 40 ft. high. The ore was leveled, and a plank floor was laid and covered with linoleum. The stope was lighted with electricity, and the walls were beautifully decorated.—The shaft at the property of the Bonita Copper Co., in Lone Star district, is now 80 ft. deep. This was started about three weeks ago. A steam hoist will be installed soon. About 25 men are working at the property.—The Arizona Amalgamated Co. has obtained an extension of the bond upon the properties which they are developing.—The Bacon & Langerman silver property has a large amount of ore ready for shipment; this was extracted in the course of development. Owing to the fact that the smelters at Douglas cannot receive much of this ore at present, only a few carloads will be shipped each month.

MARICOPA COUNTY.

Very few of the mines near Wickenburg have shut down completely but, owing to the slump in copper, many of the copper properties have followed the example of the large copper mines of the country and have laid off about half the miners. There is practically no change at the gold properties, as most of them are working their usual force of miners.—The main shaft at the Monte Cristo is now 180 ft. deep and is still in good silver ore. There is very little water in the shaft, although some of the old workings nearby are flooded. When a depth of 200 ft. is reached, cross-cutting will begin.—The machinery for the mill on the Monarch property has arrived and will be installed immediately; it is expected that this mill will be running by the first of the year.

MOHAVE COUNTY.

H. G. Hellron has been made superintendent of the Gold Road mine to succeed S. R. Porter, who resigned recently. The mine has been placed on a dividend-paying basis and considerable gold ore has been blocked out. There is much broken ore in the stopes. A dissention has arisen among the stockholders regarding the building of a modern mill. The American stockholders want to build a modern plant, while the French oppose this and wish to continue to treat the ore in the old mill. It is possible that the mine will close down on account of this disagreement.—At the Enterprise mine, 15 miles east of Kingman, a body of good copper ore has been discovered in the cross-cut from the east drift on the 120-ft. level.—The Tennessee mill at Chloride has been running regularly on the old mill tailing. A good zinc concentrate is being made by the jigs. The static machine does good work but another separator will have to be put in to treat the intermediate sizes from the crushers. As soon as this arrives the mill will be kept constantly on good ore.—Regular shipments of lead concentrate are being made from the Banner mines at Stockton hill.

At the Idaho mine near Cerbat mining has been resumed; the mill is now in readiness to treat the zinc ore from this mine. A carload of zinc is ready for shipment. John Boyle Jr. is superintendent.—At the property of the Victor Gold M. Co. near Vivian grading has begun for the new cyanide mill.

PINAL COUNTY.

At the property of the Alta M. Co. near Mineral hill the new air-compressor, hoist, and pumping machinery have been installed and sinking will be resumed in the Black Cop-

per shaft with machine-drills.—The Saddle Mountain M. Co., whose copper mine is near Christmas, has filed with the County Recorder a mortgage on their mine and smelter for \$1,000,000.—The shaft at the Oklahoma mine on Mineral hill is now 100 ft. deep. The new No. 9 Cameron sinking-pump is able to take care of the increased flow of water which has been cut in the shaft.—At the Cochran mine 25 men are working and much development work is being done.—The Imperial Copper Co. is employing between 350 and 400 men at its mines at Silverbell and its smelter at Sasco. It is expected that the smelter will be completed by Jan. 1; its capacity will be 350 tons. The concentrator will not be completed until quite a little later.

CALIFORNIA.

BUTTE COUNTY.

The recent strike made near Kimshe, in the claims owned by W. P. Lynch, J. F. Lynch, O. C. Barber and others has proved very rich. This property is situated on Snow's Table Mtn. This mountain is capped by lava flows, 250 to 300 ft. deep. A cross-cut adit was run to cut a supposed deep channel. This cut the channel and the gravel proved very rich, indicating that it was the source of the gold mined in early days in the ravines of Snow's Table Mtn. In the early sixties about 100 men were working on the gravel in these ravines; several hundreds of thousand dollars were produced.

NEVADA COUNTY.

Now that the air shaft at the California mine has been finished, the chute of ore found in this shaft will be developed. Good ore is being mined in the south drift of the lowest level. The Idaho-Maryland mill has been leased for the purpose of treating 200 tons of ore from this mine.—Development work has been resumed at the Banner mine; at present 16 men are working, but the force will soon be increased. The new shoot of ore found in the south drift of the 900-ft. level is 5½ ft. wide. Two shifts are now working at the Idaho-Maryland. The new shoot discovered on the 500-ft. level, and about 1,500 ft. east of the shaft, is looking quite well; the ore is quartz carrying sulphides and some free gold.—At present the Sultana company is greatly hampered by the lack of power, so it proposes to build a power plant of its own. The Prescott Hill shaft is now 1,140 ft. deep. This will be sunk to 1,500 ft., where a station will be cut and a large electric pump will be installed.—The new 10-stamp mill at the Ancho mine, near Graniteville, is now completed. A good boarding-house has also been built. During the winter the mill will be run on the ore that comes from development.—At the Delhi mine rich ore has been found in the shaft that has been sunk from the east drift of the lower adit level; this shaft is now 300 ft. deep. Most of the ore being treated in the 20-stamp mill is being stoped from this part of the mine. At present 35 men are working at the mine and mill; ten other men are repairing the Bloody Run ditch and flume, which furnishes part of the water used at the mill. The vein at this mine is from 2 to 5 ft. wide.—At the Champion mine a vein of ore 6 ft. wide has been found in the hanging wall south of the shaft on the 800-ft. level.—At the Marcotte mine the 5-stamp mill is being kept busy with ore from the adit.—Work has been resumed at the Banner mine, which has been shut down since Nov. 20. This mine is owned by Mrs. L. S. Huntington, of New York, and is being worked under a bond by E. C. Vorheis, Fred. W. Bradley, and others. Last month a vein 5½ ft. wide was found on the 900-ft. level; a drift 23 ft. long has been driven following this vein. This ore is said to average \$20 per ton. In 1865 to 1872 this mine was worked to a depth of 600 ft. and produced a large amount of ore. The vein was faulted on that level. After desultory attempts to find the vein the mine was abandoned.

(Special Correspondence).—Sinking at the Central shaft has been temporarily suspended owing to an injury to the hoisting engine. As soon as the damage is repaired sinking will be resumed.—It is reported that the Conlan mine will be re-opened at an early date. The general manager for the company is now in the East raising funds to work the mine, and is expected to return here soon with ample capital to proceed with development work.—The electric

plunger pump for the Prescott Hill shaft is nearing completion at the foundry of the Taylor Engineering Co. The pump will have a capacity of 500 gal. per min.—Considerable exploration work is under way at the Pennsylvania-W. Y. O. D. mine and several men are employed. Bennet Opie is superintendent.—The working force at the Kenosha was recently increased, and some rich ore is being developed.—At the Brunswick excellent milling ore is being extracted and the mill is running on good ore. Considerable development work is under way.—Samples of ore, assaying from \$3.50 to \$15 in gold per ton, have been taken from shallow holes on the Buena Vista ranch.—Norman E. McGregor has struck some good ore on an extension of the Reese Ravine quartz mine, near Poker Flat. He has located several claims in that vicinity.—The Lulu, Gold Buck, and Nim's Choice claims have been located in the Meadow Lake section.—Men are pouring into the county from all sections, with the expectations of securing employment. The labor field here is overcrowded at present, and many of the men will have to seek work elsewhere.

Grass Valley, Dec. 9.

SHASTA COUNTY.

At the Mountain Copper Co.'s smelter at Keswick 10 men have been at work, since the smelter shut down, cleaning up matte and loading it for shipment. The work has been

to try to find a continuation of the rich vein found in the nearby Tightner mine. L. P. Woodbury is superintendent.—Several miners have been laid off at the Young America drift mine; a few others have quit of their own accord. The men are said to have received no pay for the last two months.—The adit at the South Fork mine is steadily advancing. F. W. Kuhfeld is superintendent.—A. L. Wilson and J. S. Frye have found good pay-gravel in their drift mine at Cold Springs. This channel is thought to be the same as the upper channel of the Bald Mountain Extension property.

TRINITY COUNTY.

Only 45 men are working at the Bonanza King mine and mill, near Trinity Center. The surface improvements have been completed, so all those men have been laid off.—The mill at the Golden Jubilee mine near Carrville has been finished.—The Nash mine has closed for the winter.

TUOLUMNE COUNTY.

At the Soulsby mine the change-house was burned last week. About 20 men are working at this mine.—The Republican mine near Jacksonville has been bonded to F. B. Keever and J. R. Bryson, who represent Boston people; work has been resumed at the mine.

YUBA COUNTY.

The Iron Mountain Copper mine near Fernley has closed down; 10 miners were employed at this mine.—Considerable development work is being done at the Blue Point mine, owned by M. Marshall and others.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence). The vein in the Sunburst mine has widened from 4 ft. to 6 ft., the drift is now 40 ft. long, and stoping will begin soon. The ore carries considerable silver glance and gray copper. At the East Argente the Corwin vein has been intersected in the Tobin adit. At the Muscovite mine the old workings have been cleaned out and placed in good condition; the lower adit is to be extended 200 ft. A body of lead ore is showing in this adit which measures 10 in. across and carries 19 oz. silver and 60% lead.—Tests are now being made in Denver upon the ore taken from where the Deming lode is intersected by the Moline adit. The first tests show a high extraction of gold and silver. The Democrat Mountain Co. will probably erect a plant with a capacity of 50 tons per day. It is intended to extract the gold and silver by amalgamation and then to concentrate the tailing on tables, so as to save the lead, zinc, and iron. Jerome Smith, of Georgetown, is manager for the company.—On the 150-ft. level of the Maud S. mine, on Douglass Mtn., a streak of rich silver ore has been exposed on the hanging-wall. The adit has been cleaned out and retimbered and is now being driven forward to intersect the vein at a depth of 150 ft. below the old workings. Steady shipments of ore are being made by M. Kelly, who is working the property under bond and lease.—Stoping is in progress upon the Edinburg vein, which was cut 300 ft. from the entrance in the lower adit. On the footwall a streak of lead ore 18 in. wide is showing; this ore assays \$22 per ton in silver and lead. On the hanging wall several feeders of high-grade ore are showing.—The compressor at the Sidney adit has been closed down for the winter, owing to insufficient water supply. A force of 12 men is developing the three veins in this property and considerable ore is being extracted. The adit was advanced during the summer months 975 ft., making a total distance of 2,950 ft. Regular shipments are being made of ore from the blind vein, which was cut 2,125 ft. from the portal. M. Sidney, the manager, states that work will continue during the winter.—A rich strike has been made at the Centennial claim, on Leavenworth Mtn., where David Kennedy, the owner, a few days ago found a rich pocket of gold-bearing ore only 8 ft. below surface. From 8 to 10 sacks are being sorted daily. The mineral is showing in the breast of the cut as well as on the floor; sinking is to be started soon.—Work was resumed this week upon the Plate property, situated on Griffith Mtn. The adit is to be extended for 100 ft. as considerable scattered mineral is showing in the head-

Map of California.

finished and these have been laid off. There are about 50 men on the company's payroll. Work continues at the mine. The foundry is being run on work for the Martinez plant and on custom work for the Mammoth smelter at Kennett.—A majority of the stockholders of the Balaklala Consolidated Copper Co. have agreed to the plan for reorganization through a syndicate, which will make an assessment of \$2 per share; this will amount to \$1,050,000.—The Annie mine in the Stillwater district has been sold to Joseph Jaegel.

SIERRA COUNTY.

Work has been resumed at the West Point drift mine; the adit is being driven through the channel to cut the White Bear vein, supposed to be about 50 ft. beyond the face of the adit.—Surface work has been suspended at the Sovereign mine. An air-compressor is being installed; work will then be resumed in the lower adit.—At the Red Star mine, near Alleghany, several buildings are being erected. The electric light plant has been completed and the adit has been wired. Three shifts are working in this adit, which is being driven

ing. Many years ago some exceptionally high-grade gold ore was mined near surface in this property. Wm. Aldred is owner of this mine.—A 6-in. streak of rich silver ore has been found in the Vorhees vein, on Democrat Mtn. The discovery was made 150 ft. from the adit entrance; the vein has been opened for 20 ft. Three tons of the ore were delivered to the local sampler last week. Robert Fisher, of Georgetown, is owner of the mine.—Sprouse & Co., leasing on the Commonwealth vein through the Wilcox adit, are mining considerable silver-lead ore. An average of one carload is shipped weekly, but it is hoped to increase the output during the next two weeks. A stope is 100 ft. long; the streak of ore is from 12 to 18 in. wide and assays \$40 per ton.—E. E. Grubb has taken a lease on the Annie May property, on Columbia Mtn. The adit, which is 70 ft. long, is to be driven 200 ft. farther. Several patches of sulphide ore are showing in the heading. The Annie May vein runs parallel with the Stemminder vein, where considerable rich silver ore has been mined during the past six months.

Georgetown, Dec. 3.

ESMERALDA COUNTY.

Federal troops arrived in Goldfield Dec. 7; these were sent from California. General Frederick Funston, commanding the Department of California, has gone to Goldfield to view the situation. Nevada is the only State in the United States not to have a State militia—a very fortunate circumstance at this time. All citizens, unionists and capitalists, respect Federal troops: they know that such troops are commanded by impartial officers, who have been trained to do their duty; they know that Federal troops mean, if they shoot, to kill. No local partisanship affects Federal action. We will be greatly surprised if violence is attempted by the union miners when the companies try to resume work at the mines. The controlling element in the Union at Goldfield is as wild and unscrupulous as any that was in Cripple Creek. The outcome at Goldfield when compared to the history of the strike at Cripple Creek will furnish, in our opinion, a conclusive proof of the superiority of white Federal troops over State militia in maintaining order in strike regions. Shortly after the arrival of the Federal troops the Goldfield Mine Owners' Association adopted resolutions announcing their determination to open their works on Thursday, December 12; they will operate on a reduced wage schedule and refuse to employ any miner who does not first renounce all affiliation and allegiance to the Western Federation of Miners. This is the long expected challenge to the Miners' Union and to the socialistic agitators from Colorado and Idaho, who have thrown themselves into this last bitter fight for supremacy in the Western Federation of Miners. The paragraph of the resolutions relating to the employment of union men is as follows: "That no member of this association employ in or around his mine or around his mill any member of Goldfield Local Union, No. 220, of the Western Federation of Miners, or of any union connected with or affiliated with said Western Federation of Miners, and that all men hereafter employed by any member of this association in or around his mine or mill be required as a condition of his employment to sign a written contract which contains an agreement that the miner is not now and will not be during the time he is working a member of Goldfield Miners' Union, No. 220, of the Western Federation of Miners, or of any other union in Goldfield or elsewhere that is directly or indirectly affiliated with or has any connection of any kind, nature, or description with said Western Federation of Miners."

The rate of pay is fixed as follows: Miners \$4, reduced from \$5; machine-men \$4, reduced from \$5; chuck tenders \$3.75, reduced from \$5; muckers \$3.75, reduced from \$5; ear-men \$3.75, reduced from \$5; top ear-men \$3.75, reduced from \$5; pump-men \$4, reduced from \$5; timber-men \$4.50, reduced from \$5; carpenters \$5, reduced from \$7; machinists \$5, reduced from \$6; engineers (licensed) \$5, reduced from \$6; electricians \$5, reduced from \$7; head blacksmiths, \$5.50, reduced from \$6; blacksmiths, \$5, unchanged; tool-sharpeners, \$5, unchanged; blacksmith helpers, \$4, unchanged; surface laborers \$3.50, reduced from \$4.50; amalgamators \$4.50, reduced from \$5; vanner-men \$4, reduced from \$5; labor \$3.50, reduced from \$5.

To answer the arguments that have been made by the miners that living in this camp would be impossible under a reduced rate of pay, the mine owners have announced their determination to cut the cost of living in Goldfield 20%. If the merchants maintain a stubborn attitude—and indications are that the new policy will be bitterly antagonized by the storekeepers and restaurant men—the association promises to construct and operate a general merchandise store or stores and boarding-houses "that will guarantee to the men employed in the mines and mills a reduction to this or even a greater amount." The opening of the mines on Thursday is expected to mark the opening of a bitter industrial struggle. The mine owners believe that they will have no trouble in drawing heavily from dissatisfied members of the union; and, in case the striking miners stand firm and refuse to go back to work on the operators' terms, men from outside sources will be obtained. The secretary of the association, William M. Erb, announced Dec. 10 that he had received applications for work from nearly every mining camp in the West, and he anticipated not the least difficulty in securing miners to fill every vacancy at every mine. John H. Mackenzie, managing director of the Consolidated company, has stated that in less than a year the Consolidated will have in operation a mill with a capacity of 500 tons per day. The present mills and numerous experiments on the ore have shown that Goldfield ores can be treated in the district efficiently and far more cheaply by cyanidation than by smelters. The company will make itself independent of the smelters and decrease its dependence on the railroads as much as possible.

The Goldfield employees of the Nevada-California Power Co. struck Dec. 11, refusing to accept the reduction from \$7 to \$5 per day. These are principally maintenance men and linemen. The electrical workers are affiliated with the American Federation of Labor and have no connection with the Western Federation of Miners; they had refused to strike in sympathy with the miners. This strike in itself will not affect the bringing of power from Bishop, California. As yet the men patrolling the power-line have not been notified of any reduction in wages; they will probably quit if so notified. In that case the power company would be greatly handicapped in furnishing the mines with electricity; most of the mines depend on electricity for power.

NYE COUNTY.

The ore shipments from the Tonopah mines for the week ending Dec. 5, as reported by the Nevada Ore Purchasing Co., were as follows: Tonopah company, 1,253 tons; Tonopah Extension, 195; Midway, 198; total, 1,646 tons. The Tonopah company sent 2,710, the Belmont company 1,200, and the Montana-Tonopah 1,100 tons to the mill. The total output of the Tonopah mines was 6,859 tons of an estimated value (assuming shipping ore worth \$70 per ton, milling ore \$30 per ton) of \$279,730.—Frank A. Keith has resigned as general manager for the Tonopah-Belmont company and will in future be the consulting engineer for the company.—The Montana-Tonopah 40-stamp mill is crushing at its full capacity, its output averaging 1,100 tons per week. Some rich ore is being added to the ordinary milling ore. Much development work is being done and the ore reserves are being rapidly increased.—At the Montana Extension the face of the west drift of the 600-ft. level is still in good ore; stoping continues on all levels above the 600 and the usual tonnage is being shipped. On the 1,050-ft. level the north cross-cut has as yet failed to cut a good orebody.—At the West End Con. the vein on the 200 and 275-ft. level is being prospected with good results. The customary tonnage is being stoped from the 400-ft. level. Early next month sinking in the new shaft will be resumed and continued until a depth of 500 ft. is reached.—At the Jim Butler the new air-compressor is working smoothly; air-drills are now being used on all the levels.—The strike at Goldfield has not affected Tonopah in the least.

At Round Mountain a vein, 4½ ft. wide, of good milling ore has been found in the Johnson lease on the Daisy property.—The Round Mountain Hydraulic Co. has completed its pipe-line to Jefferson canyon and the first monitor is now in operation; three monitors will eventually be used.

Heretofore ground sluicing has been employed; it is said that the clean-up from this sluicing was about \$500 per day. —'Dry washing' will soon begin on the Combination claim.

Another important orebody has been developed at Rhyolite this week. The new adit of the Golden Sceptre property has cut the Hobo vein at 230 ft. from the portal and at a depth of 150 ft. from surface. The cross-cut has passed through 8 ft. of lode without any signs of the other wall. The ore is a manganese-stained quartz so characteristic of Rhyolite. As yet no assays have been made on this ore, but 'pannings' indicate that the ore is of good milling grade. This adit passed through two other veins 10 to 15 ft. wide before cutting the Hobo, but they were not prospected. Driving both ways on the vein will begin immediately. —It has been announced that the Goldbar 10-stamp mill will be completed by Dec. 15. The only possible cause of delay will be the failure of the Nevada-California Power Co. to have the power-line to the mill completed by that date. Only a small amount of development work has been done at the mine while the mill was being built, but by Dec. 1 a full force of miners will be working again. —The Mayflower ores are being tested at both Los Angeles and Denver, and it is understood that, when the company is thoroughly satisfied as to the process best adapted to their treatment, a

Map of the New Mining Districts of Nevada and California.

contract will be let for a milling plant. The Mayflower has already a large amount of milling ore blocked out and the management thinks that the installation of a mill is thoroughly warranted. —Phillips & Moesser are preparing a shipment of ore from their lease on the Gibraltar, and will send it out as soon as the smelters are in a position to handle the ore. They have over four tons of high-grade ore which will assay about \$300 per ton; the rest of the consignment will be made up from lower-grade material which has accumulated on the dump. The lessees say that if there were a custom mill in the district that they could furnish a large amount of excellent milling ore. —T. W. Brock and associates have bought a large number of shares in the Tecopa Consolidated company. It is also stated that a smelter will be built at Beatty to treat the ore from this lead mine, which will be mixed with silicious ores from Rhyolite and Goldfield. The Tecopa mine is only producing about 60 tons of ore per day, as the company decided to curtail the output until the smelters made more prompt settlements. The company intends to build a spur from Tecopa siding, on the Tonopah & Tidewater railroad, to the mine. —Al. Myers and

associates have bought the control of the Transvaal of the Nevadas M. Co., whose properties (the Transvaal and the Congo) created quite an excitement when they were first discovered, about 18 months ago.

BRITISH COLUMBIA.

The shipments from the mining district of British Columbia for the past week were as follows: Boundary, 19 tons; Rossland, 6,400; Slocan-Kootenay, 3,705; total, 10,124 tons. —The Britannia mine has shut down, and it is stated that the Crofton smelter will be blown out in a few days. —The employees of the Trail smelter voted to return to the wage schedule in force prior to May 1. This vote insures continuous operation of the Rossland mines and the Trail smelter. —Wages have been reduced in the Slocan district to those prevailing prior to the advance made this summer. The miners have accepted the reduction.

BOUNDARY DISTRICT.

The Duncan mine, on West Fork, has shipped another car of ore. —At the Mother Lode mine, in Deadwood camp, only 16 men are working. —Driving has begun on the 300-ft. level of the Crescent mine, in Skylark camp. Ten men are working at the mine; M. I. Feeney is in charge. —At the Granby mines a complete underground survey is being made, as it is now possible to survey many places which can not be when mining is being done. C. M. Campbell is in charge of the surveying. —At the Brooklyn mine this week the pumps are again being driven by electricity; during the last month steam was used. —The spur from the C. P. R. tracks to the Gold Drop-Curlew claims, adjoining the Snowshoe mine, has been finished.

ROSSLAND DISTRICT.

The output of the Rossland mines for the week ending Nov. 30 was as follows: Centre Star, 3,635 tons; Le Roi, 2,240; Le Roi No. 2, 525; total, 6,400 tons. The new wage schedule at the mines went into effect Dec. 1. The wage of shovelers will be \$3 per day instead of \$2.75, as stated last week. The wages of shovelers were advanced from \$2.75 to \$3 May 1, and as that wage prevailed in May and June the wages of shovelers have only been reduced to \$3. —Considerable development work is being done in the mines of the Consolidated company. —At the Giant mine they are driving on the vein. The adit is being extended at the California mine; the shaft being sunk from the adit is now 150 ft. deep. —The operation profits of the Consolidated Mining & Smelting Co. for the year ending June 30 were \$484, 676. This company owns the Centre Star, War Eagle, and St. Eugene mines and the Trail smelter, as well as other but smaller mines in British Columbia.

MEXICO.

JALISCO.

A good body of copper ore, carrying some gold, has been found on the lowest level of the Carrizo mine, near Autlan. The ore is a sulphide and about 7 ft. wide. The El Refugio mine, near the Carrizo, has been bought by Stanislaus Ossolinski, representing a Chicago company. The ore at this mine is also a gold-bearing copper ore. Both of these mines are in the Ojo Verde barranca, far from a railroad, but an easy outlet can be obtained by means of a wagon road to Chamela, a port on the Pacific Ocean.

SONORA.

At present 500 men are working at the Greene-Cananea properties. —The Fay-Cananea company has acquired from the Cananea Eastern Co. its group of copper claims on the south slope of the Ajo Mtn. Over 1,000 ft. of development work, mostly adits, has been done at this property. Ten cars of ore assaying 10% copper were shipped from one orebody. The Fay-Cananea also purchased the Dorotea group a short time ago. —A small force of miners is working at the Democrata mine, doing development work. —El Tigre mine is working a full force of miners and some construction work is being done. —The Los Alosis mine, in the Tabatacochi district, has been sold to E. F. Kelly, of Los Angeles, Cal. The Los Alosis mine has been worked steadily for two years, and the ore shipped has paid for all development work.

Special Correspondence.

London.

A Nice Question Nicely Solved.—The Tomboy and John Herron.—Boston Con.—The Issue of Debentures.—Consolidated Gold Fields.

Is it right for a mining engineer while in the service of a company or of an individual mine-owner to take up adjacent claims in his own name? This is a question which is often asked in London, and the answer all depends on the point of view. Some engineers will say that as their services are only engaged for the management of a particular mine, the owner's claim on their services is confined to that particular mine; while others, with a larger-hearted conscientiousness, say that the whole of their mining knowledge and experience is engaged to their employer. It all depends upon the wording of the agreement between the engineer and the employer, but I am referring specially to the case where the agreement is dealing solely with the engagement in connection with a particular mine. The question has been raised this week by the mention of the case of John Herron, formerly manager of the Tomboy mine, at Telluride, in Colorado. Mr. Herron is an altruist and believed his duty to be to do everything in his power to promote the success of his company without considering his own personal advantage. It will be remembered that the Tomboy mine was floated in London some nine years ago, and within a year or two began to show signs of exhaustion. Mr. Herron early recognized the serious position of things, and without delay made a thorough investigation of other properties adjoining. He obtained a free option on behalf of his company on the Argentine group for 18 months, calling for the payment of \$60,000 at the end of that time. During those months he took out ore that yielded \$100,000 profit and disclosed further ore supplies that would yield a further \$250,000 profit. Up to the present time a total of over 500,000 tons of ore have been taken out of the Argentine, and a net profit of £343,000 obtained. There are ore reserves sufficient to last for five years now in the mine, and development work continues to be successful. It is estimated that for some years to come the dividends will average £100,000 per year. This is what Mr. Herron brought the company, and so far, the only extra honorarium he obtained was £2,000. Mr. Herron retired a year or two ago, broken in health, owing to the anxieties of the great strike, and owing also to some extent to the high altitude not suiting his constitution. It is with great pleasure, therefore, that I am able to record that the directors and shareholders are taking some steps to liquidate their obligation to Mr. Herron. At the stirring appeal of R. T. Bayliss, they have agreed to grant him an annuity of 1% on the net profits of the mine. This will work out at about £1,000 per year, judging by the figures given above. As Mr. Bayliss says, it is not much, not nearly as much as he would give him. For his sake, we hope that the mine may last a long time, and that he may recover his health in order adequately to enjoy it.

The directors of the Boston Consolidated Copper & Gold Mining Co. are not very popular with their English shareholders at present. This company is an English one, and it holds practically all the shares of the American company of a similar name, which owns and directs the operations at Bingham, Utah. A bare majority of shares in the English company is held by the controllers, so that everything can be rushed through by recourse to a poll, without explanation of the policy or position of the company. For instance, the creation of 100,000 new shares and the issue

of £252,000 of new debentures has just been authorized in this way. A meeting of shareholders was called this week in order to comply with the law, and the proposals were put before the shareholders with practically no explanation. The shareholders present were mystified at the position, and in absence of suitable explanation voted against the directors' proposals. The directors, however, mentioned that they had proxies for 311,000 out of 548,480 shares issued, so that settled the matter, and the shareholders present withdrew in disgust. The remarkable part of the affair is that only three or four months ago the directors announced the impending repayment of the debentures still outstanding, yet now they come and create a further issue of quarter of a million pounds. The mine and the metallurgical plant belonging to the company are well known in the technical world. In fact, both are too big and prominent features of the landscape for it to be possible for the directors to prevent the publication of information respecting them. But no official statement of the exact position of the company is ever issued to the shareholders. The shares have always been talked high in London and they have stood at £8 per £1 share. Six months ago they were £6, and now the quotation is below £2. It is foolish to give explanations of phenomena when we do not know the inside facts, but the appearances are that English shareholders who acquired vendors' shares at a high price are getting frozen out by the same people now that the mine is nearing a remunerative stage.

The Consolidated Gold Fields of South Africa, Ltd., is paying a dividend on the ordinary shares at the rate of 12½% for the year ended June 30 last, disbursing in this way the sum of £250,000 on the capital of £2,000,000. In addition the company paid the usual 6% preference dividend on 1,250,000 preference shares and 5½% interest on £350,000 debentures, besides redeeming £25,000 of debentures. During the previous two years no ordinary dividend was paid, nor was one paid during the years 1898 or 1901, and the year 1902-3. Though dividends were absent some substantial profits were made and nearly £2,000,000 added to the reserve fund. Of this sum, one-half is in Government securities and the remainder used in the business of the company. In addition to these amounts placed to reserve, considerable sums have had to be written off for depreciation in the market value of shares held in various companies. For instance, in the year under review, no less than £634,491 has been written off in this way. In the early days of the company, very large profits were made by flotations of subsidiary companies and by market transactions in shares in these other companies. More recently, however, hardly any business of this sort has been possible, and the income has been derived from the output of gold by the companies in which the Gold Fields holds interests.

Mexico.

Virginia Makes Payment.—New Mill.—Work at El Favor.—Makeever Bros.—The Jalisco Mining Co.—El Tajo.—The Navidad District.—Quicksilver.

It is learned with pleasure that the rumor to the effect that the Virginia & Mexico Mine & Smelter Co. would not be able to make payment, because of financial conditions, has proved false, and that the payment due last week has been met and the plans originally intended are to be carried out. The property referred to is the Cabrera, in the Hostotipaquillo district north of Ezatlan, State of Jalisco, which the Virginia & Mexico M. & S. Co. obtained last March from Carlos Romero, of Ezatlan, and is a part of the large area acquired by the latter last

been for several months, the tendency is to tighten operations and curtail expenditures. During the past week the company closed its big sawmill at Hamilton, and for the first time in years stopped work in the logging camps near Como. It is expected that other mills will be closed, and the prediction has been made for several months that by the first of January all the mines and smelters, mills, and logging camps of the Amalgamated in Montana would be closed tight. [Later dispatches state that all the Amalgamated mines have been closed down except those of the Boston & Montana group.]

Some of the new companies in the Butte district are still active and apparently have sufficient funds for the present. The companies in which W. W. McDowell and his associates are interested, are pushing development work. These are the Colusa-Leonard Extension, the Butte & London, and the Pilot-Butte. The last named made a high record for shaft-sinking in November, the total depth attained during that month being 125 ft. For a three-compartment shaft it breaks all records in the Butte district. At the end of the month the total depth of the shaft was 345 ft. All but about 20 ft. of it was through hard rock. Three veins have been cut in the Pilot-Butte shaft, the last one being encountered at a depth of 300 ft., the vein being about four feet wide. At a depth of 500 ft. cross-cuts will be driven to the veins and the expectation is that pay-ore will be found.

The Butte & New York Co., which is directing the work on the claims of the Butte-Milwaukee Mining Co., is still going on with the shaft-sinking on the Colonel Sellers and has reached a depth of 740 ft. At the 700-ft. point a large station has been cut and a 30,000-gal. tank is being placed there. Very little water has thus far been found and the placing of the tank is merely a precaution. The Colonel Sellers shaft is one of the best constructed three-compartment shafts in the district, and is in solid granite all the way down. Although the management of the company believes that ore can be found on the 700, it is the intention to do no exploration or mining above the 1,000-ft. level. A new first-motion Nordberg engine has been ordered by the company and will be on the ground shortly. A number of improvements have recently been made on the surface.

Later News.—Amalgamated Mines Shut Down.

At a meeting in New York last Saturday the directors of the Amalgamated Copper Co. decided to stop mining at all of the mines of the subsidiary companies in Butte with the exception of three mines of the Boston & Montana Co., and to close the big Washoe smelter at Anaconda indefinitely. As the same interests also control the North Butte and Butte Coalition, the mines of those companies were also closed completely. About 3,000 more men are thereby laid off at the mines and smelters, making the total laid off about 10,000 men. It is announced that the output of the three Boston & Montana mines would be somewhat increased and that the copper production of the Butte district would not be materially reduced below that of the past month. The Washoe smelter and the mines of the Anaconda, Butte & Boston, Washoe, Parrot, Trenton, Butte Coalition, and North Butte companies are affected by the farmers' suits for injunction now pending in the United States Court against the Washoe smelter. In view of the recent decision of the United States Circuit Court of Appeals in the case of the Utah smelters, it is feared that an injunction against the Washoe smelter will be granted, and that the present shut-down only anticipates a forced suspension by several months. If the injunction is granted, it will mean a suspension for a long time, probably several years. If the suspension depends only on the copper

market, there may be a resumption as soon as the demand for the metal improves. The orders from New York are being carried out and by the first of January the shut-down will be complete. The Boston & Montana is working only the Mountain View and East Colusa mines and a portion of the Pennsylvania, and is shipping about 1,100 tons of ore per day. The only other producers in the district now are the mines of W. A. Clark, which ship about 600 tons of ore per day, and the mines of the Pittsburg & Montana Co., which yield about 125 tons per day.

In the absence of John D. Ryan and John Gillie, heads of the Amalgamated Co. in Montana, there is no one to speak with authority for the company, but it is asserted that the shut-down is merely a transfer of production to the Boston & Montana in the interest of convenience and economy, the ore of the Boston & Montana mines being much richer than that of the other Amalgamated mines, and that to mine the Boston & Montana ore it is necessary to ship to the Great Falls smelter, as the company has a binding contract with the Great Northern railroad for the transportation of Boston & Montana ore. However, this explanation does not get around the fact that the very highest grade of copper ore is in the mines of the Anaconda, the North Butte, and Butte Coalition. The Boston & Montana cannot mine in the Leonard and West Colusa because of the fire in those properties. The Great Falls smelter has a capacity of about 8,000,000 lb. copper per month, and the company also operates a refinery there, having a capacity of 5,000,000 lb. per month.

Salt Lake, Utah.

Cut in Wages at Bingham.—Dividends.—The Bingham and Utah Con. Smelters.—The Gemini.—Ogden Smelter Shuts Down.—

The Mine Operators' Association of Bingham has announced that, beginning January 1, the scale of wages now prevailing in that camp will be reduced, making a difference all around of about 25 cents per shift. While the announcement has been received with a good deal of dissatisfaction by the miners, it is not anticipated that there will be any trouble about it, as the mining companies can easily fill the places of the men who do not desire to work under the new regulations. It will be remembered that about a year ago the mine operators of the camp voluntarily granted the men a raise of 25 cents per day; later, another similar increase was granted and was to remain in force while copper sold at 18 cents per pound or better. The new schedule cuts wages down to where they were before the second raise. In the notice posted about the mines the operators say the present scale will be restored whenever copper gets back to 18 cents again. A small force of men quit the employ of the Boston Consolidated a few days ago when the announcement was made, but the management of the company found no difficulty in filling their places.

The Uncle Sam Consolidated and May Day Mining companies posted their regular monthly dividends for December a few days ago, the amount being \$15,000 and \$12,000, respectively. The dividends are payable on December 20 and 23, respectively.—The Bingham Consolidated smelter will be closed in about a week, and then this company will be out of the smelting field entirely. The announcement was made some time ago that the plant would go out of commission and in the meantime energy has been put forth toward cleaning up the accumulation of ore on hand.—The Utah Consolidated Mining Co. is making a strenuous effort to secure permission from the court to continue the operation of its copper smelter long enough to build another one. A mass meeting of the farmers who appeared as plaintiffs in the late injunction

suit is to be held this week at which the matter will be discussed. A conference between the committee representing the interests of the farmers in the late controversy and attorneys of the company was held last week and the coming gathering is a result of it. The management of the mining company evidently realizes that it is futile to attempt to make any further effort to keep its smelting operations centred at Murray, but it is desired that sufficient time be granted to erect its proposed plant on the Tooele county site. It is believed the farmers will agree to this. It is claimed that it would take about a year to build a new plant.

The Horn Silver Mining Co. produced 1,250,000 lb. zinc during the past year. The mine has been closed for several weeks, however, its contract with the smelters having expired, and the latter refused to renew it on the former basis of settlement.—The installation of cyanide

preparing an address which will be sent to every member of Congress, to the governors of every State, the mayors of all the principal cities, the heads of commercial bodies, and to all the principal financial centres. The members of the committee are: Mayor John S. Bransford, Governor John C. Cutler, John Dern, C. C. Goodwin, William H. King, Thomas Kearns, Stephen H. Love, Charles A. Quigley, and M. H. Walker. This is a movement inaugurated with a view to bringing pressure upon the Government to coin 50,000,000 oz. of silver as a means of relieving the present financial stringency.

Denver, Colorado.

End of Important Litigation.—The Golden Cycle Mill Resumes Work.—Activity at Cripple Creek.

The litigation which has been carried on for the past three years between the Portland Gold Mining Co. and the Stratton's Independence Co., Ltd., was brought to an end by the decision of the United States Circuit Court of Appeals at St. Louis, December 5. The Portland Gold Mining Co. loses its suit to recover the value of ore to the amount of \$400,000, which it is claimed was mined unlawfully by the Stratton's Independence Co. from the Portland mines at Victor. The suits were originally brought in the Federal District Court at Denver. Only one of the suits was tried at St. Louis, and the decision there given upholds the action of the lower court.

The headquarters of the United Mine Workers of America has been removed from Colorado Springs to Denver. District No. 15 comprises Colorado, Utah, and New Mexico, and it was decided at the national convention held in Indianapolis last October that Denver would be more accessible from all directions. The offices are in the Commonwealth block. It is to be regretted that the change was not deferred until the El Paso coal strike had been settled. The conduct of such affairs is always steadier and more conservative under the direct supervision of the chief officials of the union.

On December 5 the Golden Cycle mill was re-opened for custom work. It has taken only 118 days to rebuild and, when everything is considered, the work has been accomplished with unusual speed. The capacity of the mill is now only 450 tons per day, but by January 1 the mill will be running up to its full capacity of 900 tons per day. The latest ideas in mill construction and installation are embodied in the new Golden Cycle plant. The ore is handled automatically throughout. Conveyor-belts have been substituted for elevators and the number of bearings has been reduced to a minimum. Several of the Cripple Creek mines had to close down when the Golden Cycle mill was burned last August. Most notable of those to resume with the new mill is the Findley, which is now producing 100 tons per day.

Everything seems to favor the increased activity in Cripple Creek. Miners are already coming in from Goldfield, because of the labor trouble there. It is estimated that at least 3,200 men are employed in the camp. The increased mill capacity furnished by the Golden Cycle of Colorado City is also a stimulus. For the month of November the production was 46,300 tons with a total value of \$1,091,050. This unquestionably places Cripple Creek first in Colorado mining camps. While this is an increase in value, it is a slight decrease in tonnage, owing to a temporary lessened mill-capacity and poor railroad transportation.

An organized movement is in progress to have a geological survey made of Summit county. B. Stanley Revett is active in circulating the petition, which, when complete, will be forwarded to Washington, asking that the United States Geological Survey undertake the work.

Utah.

equipment at the mill of the Jennie Gold mine in Iron county is progressing favorably and will be ready for commission early in 1908. The company has reported a strike of considerable importance on the 175-ft. level of the mine.—The working force at the property of the Newhouse Mines & Smelters Co. has been increased somewhat, but the mine is not running on the basis that it was before the late order for curtailment.

The Gemini Mining Co., of the Tintic district, paid dividends of \$20 per share this year, making a total of \$100,000. At the annual election held recently, John Q. Packard was chosen president; Edward W. Packard, vice-president; L. S. Hills, treasurer.—The plant of the Utah Smelting Co., near Ogden, has been closed indefinitely, and it is said the owners are willing to dispose of the plant at a fair price. The plant has been a success metallurgically, but financially it has been just the reverse. The company went into active competition with the other custom smelters of the Salt Lake valley and bought a great deal of ore when copper and lead metals were much higher than they are now, with the result that a large amount of money has been tied up.

The ore and bullion settlements reported through Salt Lake banks last week were \$430,000.—As a result of the silver coinage movement inaugurated in this city recently, the committee appointed for that purpose is

Wallace, Idaho.

Morning and Snowstorm Mines Closed.—No Curtailment at the Bunker Hill & Sullivan.—Rebuilding Tailing Dam on Canyon Creek.—Federal Company Dividend.—General Developments.

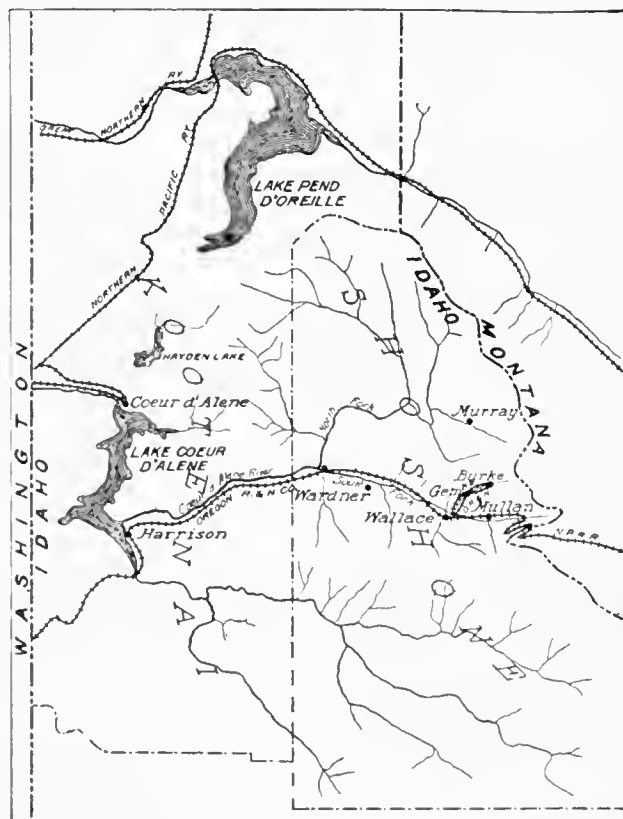

The closing down of some of the big mines has tended to cast a gloom over the district, but work on the development of the prospects is going on as merrily as ever. The closing down of the Morning mine at Mullan, owned by the Federal Mining & Smelting Co., has had a very depressing effect locally. The Morning mine is the second largest producer in the district and showed a net profit of about \$250,000 for last year. About 400 men have been thrown out of employment but, Charles Sweeny, the president of the Federal company, states that the shut-down is only temporary. The Federal company has also closed down the Corrigan mine in the Wardner district, and about 25 men have been laid off by this action. The Corrigan mine has never been a shipper and the shut-down does not come as a surprise. —The Snowstorm mine at Mullan, another of the big dividend-payers, has also closed down, and several hundred men have been laid off on this account. —A large number of prospects have also closed, but conditions are generally cheerful in spite of the gloom. Two feet of good ore has been encountered in the Mills property on Placer creek. The assay returns of the ore show $5\frac{1}{2}\%$ copper, 100 oz. silver, and \$10 gold per ton. A statement has been issued by Stanly A. Easton, manager for the Bunker Hill & Sullivan Co., the largest lead producer in the world, to the effect that there will be no curtailment in the output; this has had a reassuring effect on the Wardner district.

A force of men under the direction of Frank Franz, master mechanic of the Hercules mine, is engaged in strengthening and repairing the tailing dam on Canyon creek; it is the intention to practically construct a new dam just below the old one, so as to support it. Arrangements have also been made by the mining companies so that the O. R. & N. tracks are being moved a short distance north of their present position in order to afford additional dumping ground for the tailing. The expense of the work is being borne by the Frisco, Hecla, Tiger, and Hercules companies in proportion to the tonnage milled by each. —Work is being pushed at the property of the Liston M. Co. on Big creek, near Wardner; the adit is now about 40 ft. long. In addition to this the company has graded and built a four-mile wagon-road, connecting the mine with the O. R. & N. tracks. The machinery recently purchased from the Charles Dickens property will be hauled to the mine and installed at once. This consists of a compressor, boiler, engine, air receivers, and 2,500 ft. of iron pipe. In the meantime a contract for another 100 ft. of work has been let and development will continue without interruption. —A vein, seven feet wide, has been found in the Phedora mine; this is a high-grade lead ore carrying some silver and was cut in the drift at a point about 250 ft. from the portal. Recently a streak of ore, 10 in. wide, was found at still another point in the adit; this ore assayed about 30% lead.

A dividend has been declared by the Federal Mining & Smelting Co. payable December 15 and amounting to 7% on the preferred and 6% on the common stock; this amounts to \$210,000 on the preferred and \$90,000 on the common stock. —Work is about to be resumed on the Vienna-International mine after a shut-down of several weeks. Some time ago practically all of the company's buildings were destroyed by fire and these have been replaced by corrugated-iron structures. The mine is a

regular shipper and considered one of the most promising in the district. —The annual meeting of the stockholders of the Humming Bird Mining Co., was held at Burke and the following directors elected for the ensuing year: Harry L. Day, Dan Cardoner, M. J. Farrell, F. M. Rothrock, and H. F. Samuels. Another meeting will be held, and the company's officers will be elected from the above named directors. On account of the stringency of the financial condition it was deemed wise to suspend work in the lower adit. Part of the men were laid off and the remainder will be put on development work in the upper No. 4 adit.

David Gross, manager for the Temple M. Co. at Burke, has secured control of the Golden Winnie property near Murray. The amount paid has not been made public; it is understood that a company will be incorporated and

The Coeur d'Alene, Idaho.

shipments from the mine commenced at once. The mine is a valuable one as large deposits of tungsten are developed in it; some of these assay as high as 40%. The mine has been handicapped to a large extent by want of railroad facilities but the assurance of the building of the Idaho-Northern line into the Murray district within the next year or so will do away with that drawback. In the meantime it is Mr. Gross' intention to erect a concentrator at once and ship the higher grade ore after hand-sorting. The New Jersey company whose property is about four miles from Wardner has resumed work after a short shut-down and is running its 10-stamp mill at half-capacity. The other stamps will be started in a few days. The new shaft is being sunk where the gold vein is cut by the lower adit. At this point the gold-bearing vein is intersected by another carrying galena; this shaft will follow the footwall of the gold vein at the point of intersection of the two lodes. A large quantity of the gold ore is already blocked out. At the property of the Shoshone M. Co. on Nine Mile a station is being cut for the electric hoist, which will be used in sinking the new shaft. A large quantity of new machinery has been ordered for the mine and the power-line has been constructed.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN cyanide practice throughout the world about the only thing universally accepted is the principle of fine grinding.

AT the Broken Hill properties, Australia, 10,000 men are employed. The Broken Hill Proprietary alone employs 3,375 miners.

SLIME TREATMENT varies extraordinarily throughout the world. In Australia filter-presses are generally used to treat slime; in South Africa, agitation and decantation; in the United States, vacuum filters.

IN THE FOUR TUBE-MILLS being installed for fine-grinding ore from the Simmer & Jack mine, 'banket' is to be used instead of Danish pebbles; the mechanical engineers of the Consolidated Gold Fields have become convinced of the advantages of using banket for grinders.

AT the Tomboy mine, near Telluride, Colorado, the large rock-drills, which take two men to work them, are being thrown out, and one-man drills substituted. David Herron, the manager, estimates that just as much work is done by the small drill, with an economy of 50% in labor and 25% in air.

SUCCESSFUL amalgamation of heavy sliming ores requires that the amalgamating plates should be given a steep pitch and have frequent drops in them so as to keep the pulp in suspension and the plates clean. In amalgamating a heavy sliming mispickel gold ore, the plates were given a pitch of 2½ in. per ft., besides being broken up into short sections.

THE ladder-ways in shafts are seldom used, therefore stagings should not be placed in the ladder-compartments for they restrict the flow of air through the shaft. If more attention was paid to the subject of ventilation and less time put on ultra-refinements of the surface-plant, the working efficiency of mine labor in, at least, the United States, would be greatly improved.

TO RE-HARDEN TOOLS that have been burned, they should first be cleaned. Then take common machine oil and forge cinders; make a bed of cinders, heat the tools, put them in the cinder bed, and pour oil over them until they are partly cooled off. Having put plenty of oil on the tools cover them with the cinders and ashes, burying them deeply. They should be left so for 12 to 15 hours.

WHILE some comment has been made on the vicissitudes of smelters, treating ore during a 'falling market,' still, as the smelters usually sell as much metal and bullion each day as will be recovered from the ore that they buy each day, this only means that their assets fluctuate by the amount of variation represented in their stock-piles. Stock-piles are generally accumulated in times of low metal prices and depleted in times of high prices.

AT the Tomboy mine, near Telluride, Colorado, magnetic separators have been installed for the purpose of treating the blende and pyrite middling left after the extraction of the lead in the first treatment of the concentrate from the stamps. This middling is roasted and sent to the magnetic separator with the result that the zinc and iron are separated, yielding a zinc product worth \$45 per ton, and a concentrate of iron containing 6 or 7% copper per ton; from five tons of middling two tons of

zinc concentrate is obtained and two tons of iron concentrate. It is estimated that this treatment of a product hitherto wasted will give an additional profit of at least \$1.15 per ton of crude ore.

THE filter-press for slime treatment still is supreme in Australia, but the vacuum filters are making inroads into its popularity. At the Great Boulder Perseverance mill experiments were made some time ago with the Moore process, but it was not adopted. Butters filter has been installed at the Sons of Gwalia mill; but the most popular filter is the locally developed Ridgway filter, which is used at several mills. The Moore process is in successful operation at Waihi, New Zealand.

THE powder bill at the Daly West mine, Park City, Utah, was reduced over a third by having all powder given to the men in the stopes by a powder-monkey. In the forenoon the powder-monkey caps the fuse and packs the powder into the pouches. In the afternoon he takes these different sacks to convenient points on each level; he then starts at the top and distributes the powder and fuse, noting the amount used by each miner. By the time one sack is empty, he has arrived where another sack of powder has been left.

THE RAND gold deposits are generally referred to as very uniform in character, but this generalization is very misleading. The reefs of the Main Reef series widen and contract, they flatten some places and steepen others; the gold content also varies, some places faults cut off the orebody, other places dikes come in to reduce the tonnage obtainable from a block of ground. Some of the mines on the Rand are wet, others are dry. It is dangerous to think that orebodies are uniform in character; their origin forbids such a condition.

CORNISH PUMPS are used at the property of the Berry United Co., at Ballarat, Australia. The diameter of the plungers of the new pump is 26 in. and there are three plungers in a depth of 600 ft. The pump has a maximum stroke of 10 ft., but it is being run at a 6-ft. stroke; the valve boxes are made in separate pieces instead of the usual H-piece; the valves are of the compound flat type. The total weight of the pump is 110 tons; its capacity is about 2,500,000 gal. per day. The old pump is 22 in. diam. and has a capacity of 1,200,000 gal. per day.

FASHIONS are as characteristic of mining as of milling. Once Tertiary volcanics were considered little worthy of prospecting, but Jim Butler discovered Tonopah and now such rocks are quite favorably considered. One district is characterized by one-man air-drills; in another district small machines are thrown on the dump. One mining company favors a Rand drill, another an Ingersoll-Sergeant, still another the Sullivan, and once in a while some company favors a Wood air-drill. Gold is where you find it; any standard make of air-drill is good.

A RIFLED PIPE-LINE, 256 miles long, is being built for the Southern Pacific Company to carry oil from the districts in Kern county to tide-water on San Francisco bay. Spiral indentations are rolled into the pipe while it is being made. The purpose of the rifling is to give the oil a whirling motion, water is added to the oil, and, as the water is heavier, it is driven by centrifugal force out against the pipe so as to form a surface layer between the oil and the pipe. The friction between the oil and this thin film of water is less than between the oil and the surface of the pipe and so the capacity of the pipe is somewhat increased and the power necessary for pumping is greatly decreased.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 19.—Editor.]

The Editor:

Sir—In regard to the series of questions given in your issue of October 5, it seems to me that, if a young mining engineer, desirous of undertaking the examination of a property involving \$100,000, be not sufficiently experienced to answer most of the questions enumerated, he is certainly not capable of undertaking the work. Young mining engineers, no matter how competent they may think they are (I can look back and see how my own head has decreased in size as the years have passed) are usually not capable of making mine examinations unless they have served a sort of apprenticeship to an examining engineer of experience. However, I submit the following answers to the questions, hoping they may be of some use to the younger generation:

1. Do whichever will pay best.
2. In case of an ordinary engagement, a formal contract is unnecessary, as the engaging of a man drawing a fee or salary such as a young engineer is likely to get, can be efficiently effected by the exchange of letters or telegrams. Here, as also with question No. 3, a great deal depends upon the sort of man with whom one is doing business.
3. It is customary to pay a portion of the traveling expenses in advance; also a portion of the fee or salary.
4. Equipment as such is certainly chargeable to expense account. The hire of surveying instruments may be charged, as most examining engineers do not keep instruments of that character. Even certain personal necessities may be chargeable, when the character of the trip is exceptional.
5. The question of traveling expenses opens up a broad field, and, having had a good deal of experience with young engineers sent out to make mine examinations, I find that what is proper is largely a matter of the individual, and the special conditions of the case. What is allowed by the employer is likely to be another matter. Speaking broadly, a man should be allowed to live in the manner to which he is accustomed, if that scale of living be not above the character of the job, that is, a man making \$100 per month should not incur traveling expenses on the same scale as the man who is making \$1,000 per month. For instance, D. H. Bacon, as head of the Minnesota Iron Co., traveled about in a private car.

(a) Tips, laundry bills, and tobacco are all legitimate expense items. Tobacco is not a luxury, though one of your correspondents states that it is. With most of us it is a necessity, due to continued indulgence; and after having succumbed to the subtle influence of the weed, we should prefer to go without a portion of our food, rather than to miss the after-dinner smoke. This applies more particularly when in the field than when one is seated in a luxurious armchair, with feet on the fender, stroking the cat, and thinking of the unfortunates who happen to be camping out at night in the cold north wind, their thoughts on the armchair, the fireplace, and the cat. A cigar is often the only thing that reconciles us to our lot, especially when we have spent weeks getting to a place to find the main workings under water, or—as often

happens—no main workings at all, except in the imagination of the Ananias who wrote the report.

(b) An examining engineer is entitled to a first-class passage on railroad train or steamer, but when it comes to "best first class," as your querist puts it, that depends on the position the man occupies. For instance, a young engineer would not be entitled to travel on the Cote d'Azur between Paris and Nice, on which the sleeping berth accommodation for one night is about \$20. Nor would he be entitled to take a stateroom with bath attached on the upper deck of, let us say, the *Lusitania*.

(c) This question reminds me of a commercial traveler whom I met in 1897 coming from Salt Lake City. He had started from Syracuse, N. Y., with \$500 for traveling expenses, and he told me he had spent \$50 to see the Corbett-Fitzsimmons fight, besides having had a 'night out' in San Francisco, all of which was to go on to the expense account under such headings as "Shaving" and "Entertaining customers." He shaved himself and did not entertain his customers. That man was a thief out of jail, one of thousands who juggle expense accounts with an easy conscience. It is obvious that no man has a right to make a profit on his traveling expenses.

(d) Young engineers should keep accounts in detail; they should insert as few incidentals as possible. An employer may think such items incidental, but not necessary to the furtherance of the business in hand.

(f) Expenses for entertaining are sometimes unavoidable, but should never be of sufficient amount to be put in as such. It is an item that is open to great abuse, and what is considered legitimate entertaining is again largely a matter of the individual, besides the drinking capacity of the man who is doing the entertaining.

(g) This depends on the distance the engineer is from his headquarters, and the amount of money that he has taken with him. If he be in close touch with his office, he should render expense accounts as often as the office desires. It is customary, where one is not too far away, to send in monthly accounts.

6. In case of mine examinations, never send progress reports of the investigation unless you are sure that they will not need revision.

7 and 8. This is merely a question of common honesty, and an engineer would be committing a breach of trust if he were to buy shares before his report reached his employer. The man who is paying the fee is entitled to the first information, and should have the first opportunity of taking advantage of it. If the engineer is of a speculative turn of mind, it is only fair to take his employer into his confidence and to get the latter's consent. After the work is completed, there is no reason why a man should not use his knowledge to his own advantage if by doing so he do not commit a breach of trust. In most speculations, he will lose his money, so, as Mr. Punch advised those about to marry, I say "Don't."

9. Generally speaking, unless considerable time elapse, the publication in technical periodicals of information gathered while making mine examinations will be more or less detrimental to the business of the man who sends the engineer out, but the advisability of doing so must be decided according to the individual merits of the case.

10. This question cannot be answered off-hand. Few engineers ever make direct and unqualified statements. Professor Egleston used to say, "It takes only one 'if' to bring you to the end of the world," and an engineer, after considering all the available data, should give a decided opinion as to the advisability or inadvisability of carrying out the particular project he is sent to report upon. He may condemn a potentially good mine, being unable to get sufficient information to warrant him

in making a favorable report, but in 999 cases out of a thousand, he will be right; so I believe that unless the information be *positive*, a report should be made *negative*.

As to clearing out old drifts, unwatering shafts, and opening up caved ground, except in case of a working option, such work is rarely warrantable at the expense of the people making the examination. Properly speaking, it belongs to development work. The owner of a property for sale should make the workings accessible to the examining engineer, because in most cases the expense of doing this is not warranted by the results obtained.

I would like to say that a young engineer—or an old one for that matter—should undertake an examination in a commercial spirit and endeavor to give value received for the money expended by his clients. His first consideration should be to spend as little of his client's money as possible, and when going on a mine, make the owners of that mine pay for everything possible. Under ordinary circumstances, the engineer should not undertake to pay for any labor or material, and he is usually entitled to transportation from the nearest railway station to the mine, unless the distances are great. He should be lodged and fed by the owner of the mine on the property.

The man who desires a report wants to know whether the information obtainable justifies him in putting up the money that is asked, and the cases are only too frequent where engineers advise their clients to expend money on prospects that do not warrant any expenditure at all. One often reads in reports that "there is every indication that the orebody will get richer and wider in depth." It takes more than the "ideal geological conditions" to make a mine. On the other hand, some men are prone to report unfavorably on everything when they are doubtful regarding any of the factors, and in their calculations they take the most pessimistic view of the conditions, their pessimism being largely due to their ignorance of the district, or perhaps it is because the mine has been condemned by other engineers before them, and they have not the courage to lay themselves open to making a possible mistake. In this way, a good property is occasionally passed over. An engineer should remain long enough on a mine to be able to say "Yes" or "No" regarding it, and taking the financial arrangements into consideration, his reply, to be of value, must be a definite "Yes" or "No." Most often his report will be adverse, but the man who succeeds is the one who can grasp the potentialities of a business and who, while giving due weight to the difficulties to be overcome, is not afraid to say unequivocally that the business is good. In no walk of life can it more aptly be paraphrased that "Wise men step in, where fools fear to tread."

C. S. HERZIG.

London, November 8.

The Editor:

Sir—Answering your questions for the benefit of young engineers, I would remark that I do not regard them as unimportant; in fact, most of them could not be answered except after years of experience, unless one can be willing to adopt the views of others which may have been communicated verbally, or by implication. Past experience governs the actions of all of us; for these same questions have come up in the career of every mining engineer. Necessarily, conditions might arise which would force the most experienced engineer to answer some of these questions differently from what he would ordinarily say. I do not think a proper and complete answer can be given to all these questions without knowing the conditions that surround each particular case. My own ideas, briefly expressed, are as follows:

1. A fee, which may be a lump sum or a *per diem* charge, is the usual and proper way for an engineer to charge for his work and it is only the older and best-known engineers who can charge a large lump sum.

2. A written contract is not necessary, but a letter is desirable and necessary, as verbal instructions are often subject to misinterpretation at some later date.

3. It is not probable that a lump sum to cover expenses could be named, but a certain amount should be asked for by an engineer, to be applied on account of expenses; and a reliable client will always do this without hesitation.

4. All the equipment necessary for the work is usually chargeable to the cost of examination, this not covering, of course, the usual instruments of precision which are in every engineer's kit. In other words, I do not think it proper to buy new barometers, compasses, and clinometers for an examination, unless the party paying the bills should specifically order that this be done, as is sometimes the case when equipment of this sort is needed at the mine. In such cases, only those articles which would be useful and necessary for the further operation of the property should be purchased, and this after specific instructions.

5. (a) All necessary expenses of travel are legitimate expense items, but certainly not such things as apply to the personal gratification of the engineer's tastes, such as tobacco or other luxuries.

(b) He is entitled to first-class passage on all transportation lines and the best hotel at each stopping-place.

(c) It is not right for him to charge the cost of anything which he does not actually use and enjoy.

(d) I do not consider it necessary for him to render an itemized expense account but be prepared to do so if asked for. Therefore, any method which he may employ of arriving at the total traveling expense, is proper, bearing in mind the hints above given.

(e) I do not see any reason for taking vouchers for expenditures made. If an engineer's employer does not rely upon his thorough honesty, no man, by receipts or vouchers, would change the character of his opinion.

(f) In the matter of entertaining men from whom it is expected to get information, some latitude should be allowed and real benefits derived should be paid for by the client, as in any other expense, but I would call attention to the fact that information obtained in this way is sometimes of questionable authenticity.

(g) Generally speaking, a statement of expenses incurred would naturally be rendered monthly in case there was any considerable amount expended other than the personal expense of the engineer. In most instances, it would probably be satisfactory to his employers to have his complete statement at the end of the examination. If exploratory work is being conducted during the examination, as might be the case in many instances, together with milling operations, for the determination of the value in the ore, it would naturally be more satisfactory for the engineer to send in a statement of his total monthly pay-roll, so that his employer might be informed in case the entire examination was likely to run up to a greater cost than was at first contemplated.

6. Periodical, or progress reports, are sure to be misleading. Positive conclusions cannot be stated until the completion of all sampling and mill-tests. The engineer's employers are entitled to such general information as may be unaffected by results obtained after further inspection, but a complete report is generally more satisfactory to the man of affairs than a series of partial and incomplete reports, which are subject to possible change or contradiction.

7. Any dealing in the shares of a company whose mine is under examination is not right until the engineer's report is in the hands of his principals. After completion of his report, there is no question but what a man has a right to buy shares in anything that suits him, but as a matter of fact the confidential relation set up between the engineer and his client does not end when a report is turned in and a thoroughly conscientious man will neither buy nor sell such shares without the knowledge and consent of his principal.

8. The examination of other properties in the same district, provided it does not interfere with his original line of employment, is perfectly proper. This would involve the separation of expense account carefully so as to prorate the same properly for his original employers. The taking of options at all by an engineer, during the progress of an examination, should not be done unless his employers wish it, or circumstances arise which make it distinctly to their advantage for him to do so. These matters touching the engineer's integrity and devotion to his employer's interest can only be decided by a rigid adherence to the rule of a perfect understanding between client and engineer.

9. Publication of a description of the district visited is certainly permissible, if his employers are notified and they do not object to such publication; but frequently any publication whatever, even of the fact that an engineer has visited the mine, is liable to prove detrimental to the business interests of the parties sending him there, and the young engineer should be distinctly cautioned against exercising his own unaided judgment in a matter of this kind.

10. It is not always possible for the engineer to say "Yes" or "No" as to the merits of a property on first examination. This is particularly true where old works require cleaning out before thorough sampling can be arrived at. It is almost invariably necessary, in the case of a large mine, to spend some money in unwatering, cleaning out old drifts, and possibly extending some of the workings by a few feet in order to arrive at accurate sampling. All these costs are properly chargeable, and the engineer must be the sole judge of the necessity for such work, but he must not be ambiguous in his statements nor "wobbly" in his conclusions. The engineer must exercise his judgment as to those matters which are positively necessary to enable him to arrive at sound conclusions, and his employers must rely upon his thorough honesty, else they would never employ him at all.

F. L. SIZER.

Helena, Mont., November 20.

The Editor:

Sir—In the 'Discussion' columns of your issue of October 19, the subject of 'Professional Customs' received attention. The queries and answers are very interesting and should be instructive to the younger members of the profession. While the ten questions asked cover a wide field, they are generalities and as such have been answered, but they suggest a friendly exchange of opinion from engineers interested in professional ethics, which is desirable. Any one of the ten questions, on closer analysis, invites liberal discussion. Take, for example, the first two clauses of question 10, "Is it always expected of the engineer to say 'Yes' or 'No' to the property? Even though the property is comparatively undeveloped, or badly opened, and the facts obtainable are insufficient for intelligent opinion, must the engineer always reach a definite conclusion?"

When all is said and done there is but one thing in a report which the would-be investor wants to know. He does not want to know whether such and such a bed

belongs to the Upper Carboniferous or to the Devonian; it matters little to him whether the ore owes its origin to lateral, ascending, or descending waters, to slow metasomatic replacement of the country rock or to the interaction of thermal and surface waters; he does not care for the fine differences between rhyolite and andesite as a country rock. What he wishes to find out is, whether he is justified in taking over the property and, if so, what returns can he expect on the investment. This is really the one object of the investigation, and for this purpose he employs the best engineer obtainable, or rather he should do so. And it is to this end that the engineer is trained; the years of study, hard work, observation, and experience must all focus on this one thing; it is the ability to determine rightly after a most careful study of the general geological and economic conditions for which an engineer is paid. He must weigh and re-weigh the merits of the property under examination, he must eliminate possibilities of failure and accurately interpret Nature's complex work. A report, no matter how exhaustive in technical detail, no matter how beautifully it may be illustrated and gotten up, no matter how fine the English, fails in its purpose if definite advice for or against the proposition is not given, or at least if the conclusions arrived at by the examining engineer are not so expressed as to leave no question in the minds of its readers as to what course to pursue. In a nutshell, a 'Yes' or 'No' answer, or a presentation of the facts that admit of nothing but a definite conclusion in the minds of the would-be investors, is essential.

For years I have made it a practice to preface my reports with my conclusions. This may seem an anomaly, but capitalists are generally busy men, they have little or no time to wander through pages of technical text unless the result of the investigation is favorable, so that a brief summary embodying the final conclusions facing the title-page is advisable. The reasoning should be sound, the *resumé* concise and clear, ambiguous terms should be avoided and but one interpretation of the meaning possible. The line of argument should be subsequently developed in the text, the basis for the conclusions clearly outlined, the why and wherefore explained, and all the factors that have determined the ultimate opinion should be dwelt on. It would be as great a piece of folly to express oneself positively without showing the reasoning for such decided opinion, as to acquaint the client with geological and economic data without pointing out their significance and what they might mean in dollars and cents.

I do not wish for one moment to belittle the importance or necessity for scientific reasoning. A report to be complete must show each step toward the final conclusion. It must be replete with detail even at the risk of being verbose. The layman investor does not like to wade through pages of mysterious and meaningless words, but it is highly probable that he will hand the report to another engineer for criticism and comment, in which case a lucid picture of existing conditions must be drawn in order that the inferences may be intelligible. It is most difficult to discuss technical detail in popular language, to express in plain English a line of argument based on scientific reasoning. The average readers of mining reports are educated men and will recognize the difficulty of the task. The logic of the reasoning will be apparent or can be determined, provided all the facts are accurately presented. Unfortunately, there is a class of misguided beings who resort to technical terms to cloak their ignorance, and it is no uncommon thing in these days of questionable flotations to find a so-called report on a supposed mining property reeking with drivel. A little knowledge is often dangerous.

I have expressed the opinion that a definite answer is required by a client from the engineer, but this presupposes that the engineer is in possession of all the details of the terms of the deal. Without this knowledge he cannot advise, or even suggest, as to the advisability of exercising the option. It is then necessary to so frame his report that those in possession of the details can, without hesitation, determine their own course. A property may be worth \$100,000 on a long-time working bond while it should not be considered for a moment, as a legitimate venture, if a cash price of twice the amount be asked. If the engineer is worthy of his hire he is worthy of his client's confidence, and all assistance should be given to enable him to intelligently size up the situation.

FRANK H. PROBERT.

Los Angeles, October 22.

[We have a few more letters to publish on this subject. No more replies to the ten questions are needed, but discussion of particular points will continue to be welcome.—Editor.]

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

Sir—Referring to your query, I had the precise condition at the Smuggler-Union of an ore containing much amalgamable fine gold but a larger amount of coarse gold, which was not amalgamable. After long and unsatisfactory experiments with various types of traps, we took pieces of 2 by 4, the length of the mortar lips, cut rectangular groove 2½ in. wide by one inch deep the length of the 2 by 4, and closed the end, making a narrow trough. This was set at the head of each amalgamating plate where the pulp dropped directly into the trough from the mortar lip, thence overflowing onto the plate.

Once an hour the battery man went through the mill, picked up each of these troughs, inverted it, and struck it on the floor, knocking the contents out and replacing the trough. From this there resulted each 24 hours two half-barrels of highly concentrated pulp, which was then worked over a mechanical *batea* bought from the Allis-Chalmers Co. The bottom of this *batea* was always covered after such treatment with coarse gold, which was then fluxed and melted down into bullion.

Coarse and unamalgamable gold that gets into a concentrate is, of course, practically lost in the adjustments with the buyer, and the above is only offered as one method which got rid of a good deal of the difficulty.

C. W. VAN LAW.

Guanajuato, October 9.

The Editor:

Sir—The query is somewhat analogous to asking a doctor to prescribe for a person on the bare statement that he is sick. As the prescription would under such circumstances, if given at all, most likely be a physic, I am inclined to say: Amalgamate the coarse gold, this being the least apt to be wrong.

If the ore is stamped, and in water, plate amalgamation, with or without inside amalgamation, depending on the ore, the stamp-duty, and the shape of the mortars, would seem a reasonable thing to try, as it is so universally used for this exact purpose. If the ore is stamped in cyanide solution, copper plate amalgamation might still be the best way to get the coarse gold. We found it so at Bodie, and find it so at the Liberty Bell, though we have to renew our plates twice a year. Muntz metal I do not think much of. It will not catch the gold that copper will, and scours too easily, though it is

not attacked by the cyanide solution to the same extent that copper is.

With large roomy mortars and granular heavy gold, enough might be caught in the mortars themselves, so as to render subsequent plate amalgamation uneconomic, particularly if the pulp were run through large pansettlers of the Washoe type, after leaving the batteries. Were this done, a few flasks of quicksilver in the bottoms of the pans would help out wonderfully.

Pretty much the only remaining thing to do would be to try the merit of the idea advocated by the Denny brothers, namely, that of re-grinding the coarse gold in tube-mills along with the coarse sand, until it *will* go into solution. Tube-mills are certainly good amalgam traps, and it would seem likely that the gold would be finely divided before leaving them. However, to answer the query categorically, I will say that I would try out the various ways of catching the particular coarse gold in question, and adopt the method showing the greatest economy from the combined standpoint of recovery and cost.

EDWARD H. NUTTER.

Telluride, Colo., October 10.

Assessment Work.

The Editor:

Sir—Replying to your invitation to the prospector, I submit the following in relation to assessment work:

My personal knowledge is confined to conditions in the State of Nevada. The laws there have been so liberally construed that it is possible for a man to complete the work of locating a claim in one day. I have personally excavated the necessary 240 cu. ft. of earth in about five hours. Where the surface is fairly level and the material for monuments is convenient, the work of surveying and monumenting the ground may be done in a few hours. I grant that this is about the minimum. Perhaps a fair average for the entire cost, including the services of a competent surveyor, would be \$50. Now, a large majority of the men who have been busy in Nevada for three years were locators of ground rather than prospectors. If they found anything of value on the surface, well and good. They will attend to the assessment work on all such ground. Never fear about that. But not in one case in ten did they ever look intelligently and honestly for values. They did their location work where it could be done easiest instead of where they would be most likely to find ore. They are now waiting for somebody else to do the rest and make their holdings saleable. Such work has from the first been a great hindrance to real prospecting. The man who could find ore, and the means to develop it, is now waiting, in hundreds of cases, for the old locations to lapse. He will do nothing until he can get the ground he wants. He knows that the present holders will never do any work. He hopes that their time will expire on the first of January next; otherwise he must wait another year.

The prosperity of Nevada for one year depends very largely upon how this question is settled. Your correspondent, Edward A. Belcher, in your issue of November 30, does not exaggerate conditions as much as you may perhaps suppose. In fact, it would be hard to overestimate either the amount of flim-flam work that has been done or the damage to the mining interests of the State that has resulted from it.

H. G. HILLS.

Denver, December 4.

'RESUE' is a Cornish mining term referring to the stripping of a vein, preparatory to breaking down the ore. It is used where the ore is narrow, rich, and frozen to one of the vein-walls.

Slime Treatment at Kalgoorlie.

Written for the MINING AND SCIENTIFIC PRESS
By M. W. VON BERNEWITZ.

At the Associated Northern mine the ore is of a schistose nature, with quartz and calcite; the valuable ore carries tellurides and iron pyrite, there being very little free gold.

The treatment consists of breaking the ore with a No. 5 Gates crusher, grinding through a 27-mesh screen in three No. 5 Krupp ball-mills, roasting in six Merton furnaces, mixing with weak cyanide solution, grinding to slime and amalgamating the coarse gold in eight Forwood-Down (improved Wheeler) 5-ft. pans, settling the slime in V-shaped boxes, agitation of pulp in five vats 22 by 6 ft., filter-press treatment in three Dehne presses, and disposal of residue by belt-conveyor.

The following is the treatment in detail of the pan product. Average screen tests of this are as follows:

Mesh.	Percentage.
On 30.....	Nil
40.....	Nil
60.....	0.5
80.....	2.5
100.....	4.3
150.....	4.9
Through 150.....	87.5

weak cyanide solution, and a water-wash of 5 minutes at 100-lb. pressure, during which time each ton of slime is washed by 2 tons of solution. The washing is done by a similar pump to that used in filling, only that it runs at 13 rev. per min. A mercury gauge is used on this pump. It sometimes happens that there is plenty of mill-water on hand, so the final water-wash is dispensed with, the press then getting 30 minutes with solution. The decrease in the assay-values of the solution during washing is:

Period.	Assay.
At start of wash.....	\$12.50
After 5 minutes.....	6.60
" 10 "	1.50
" 15 "	1.50
" 20 "	1.00
" 25 "	1.00
" 30 "	0.80

After washing, the contents of the press are dried for 10 minutes with air at 80-lb. pressure. The press is then opened ready for discharging. Two men empty 11 presses per shift of 8 hours, say 50 tons, onto a traveling horizontal belt-conveyor 18 in. wide, which feeds an elevator-belt inclined at 27°, in turn discharging onto a motor-driven swinging-boom distributor.

The time taken in the different press operations is as follows:

Kalgoorlie.

The slime from the settlers is run into the agitators with a consistence of about 1 to 1, it taking between 7 and 8 hours to fill one vat holding, say, 36 tons of dry slime. The cyanide solution is made up to 0.07%, and the consumption averages 1 lb. per ton treated. Agitation is continued as long as possible, but after 16 hours the pulp may be taken for filter-press treatment. For filling the press a Pearn pump having three plungers, 12 by 10 in., running at 20 rev. per min. is used. This is a powerful pump, and with good thick pulp it will fill a press in 10 minutes, lifting in this time about 10 tons of pulp, and charging against a final pressure of 60 lb. per sq. in. The time taken in filling may be divided as follows:

Pressure.	Minutes.
Up to 25 lb.....	4
" 50 "	3
" 60 "	1
Finishing with safety-valve blowing off at 60 lb.....	2
	10

The presses are of the wellknown Dehne make with fifty 3-in. frames for the slime, the usual cloth-covered high and low pressure plates for filtering and hand-screwing gear. They hold about 1.5 tons of dry slime each. After a press is filled, the slime is washed for 25 minutes with

	Minutes.
Filling press.....	10
Washing.....	30
Drying.....	10
Discharging.....	30
Screwing-up, etc.....	10

The rich gold solutions from the filter-press, after being clarified in a small press, pass through three zinc-boxes, and the gold (running about 890 fine) is recovered in the usual manner. Most of the solution, used in washing the presses, passes into the mill again to be used in the pans, etc. An average of three months' costs of slime treatment are as follows:

	Cost per ton.
Agitation and cyaniding.....	\$0.34
Filter-pressing.....	0.41
Precipitation, etc.....	0.12
Disposal of residues.....	0.04
Total.....	\$0.91

The mill has a capacity of about 3,700 tons of raw ore per month (say 3,200 of roasted ore) and with another 1,300 tons (previously roasted) from the re-treatment of old residue; altogether some 4,500 tons pass through the three presses monthly.

Monthly returns average about:

Ore milled, tons.....	3,700
Re-treatment, tons.....	1,300
Total value recovered.....	\$70,500
Profit.....	\$48,500

Tin Deposits of Cape Prince of Wales, Alaska.

By ALBERT HILL FAY.

*In giving a sketch of the tin deposits of Cape Prince of Wales, a short description of the geographic and climatic conditions may be of interest on account of this being a part of the world of which very little is known. As shown in Fig. 1, the Cape is in Lat. N. 65° 35' and Long. W. 168°. It is the westernmost point of the mainland of North America and across the strait one can see East Cape, Siberia, which consists of a rugged steep coast of granite cliffs.

During eight months in the year no boats can reach Cape Prince of Wales. In the summer the United States mail arrives twice a month; and in the winter there is a weekly mail service from Nome. The winter mail is carried on horse-sleds from Valdez to Fairbanks over the trail shown in Fig. 1; thence down the Yukon river to Kaltag; across the portage to Unalakleet; and along the coast line to Nome and Tin City. From Fairbanks to Tin City the mail is carried by dog-sled. The total distance from Valdez (the winter seaport) is a little more than 1,400 miles. Mail from the United States will reach the Cape in from 60 to 80 days. There is a telephone line to Nome, where it connects with the United States military telegraph line to Seattle.

The summers are comparatively cool, 60° F. being the highest temperature, while 45° is about the average from June 15 to September 15. At Cape Mtn. during at least one-half of the time there are heavy fogs and drizzling rains, which make it bad for all outside work. The wind adds to the inclemency of the weather. Freezing temperatures, with snowstorms, usually set in about September 15. Navigation for small boats from Nome is uncertain after October 20. By December the sea is usually sufficiently frozen to permit traveling by dog-sled on the ice near the beach. The winters are noted for severe blizzards of snow-ice and high winds. Yet the temperature does not drop so low as in more inland places. The lowest temperature for the winter of 1905-6 was -45° F. During such a blizzard, which may last for 10 days, it is almost impossible for man or beast to endure the icy blasts as they hurl themselves upon him from the polar regions. The changes in temperature are very sudden. In 24 hr. during January 8 and 9, 1907, there was a drop of 43°, and the maximum range for the period observed was 102°. February was a cold month, with a continuous blizzard lasting about two weeks.

During seven months of the winter the climatic conditions permit little, if any, outside work, although freighting, such as hauling ore, could be performed during about half of the winter season. Underground work can be carried on without difficulty during the entire winter, but it is absolutely necessary to get all supplies in before October 1. The ground is frozen deep, and some prospect-shafts and tunnels from 80 to 100 ft. below the surface are still in the frost-zone. No well-water has been found; and, for domestic purposes, the supply comes from thawing the snow as needed. Water can be obtained near the beach at a depth of 12 ft., but it is too salt for any purpose other than milling. A supply of water for mill use during the summer can be obtained from the melting snows on the mountains, and needs no pumping.

Any concentrating-plant in which water takes an important part can be operated only during four months in the summer, since cost of fuel will be prohibitive in winter.

Fig. 2 gives a good idea of the topography of this portion of Seward Peninsula. When the geology of the country covered by the map, Fig. 3, is interpreted we are led to the belief in a distinct eruptive period, followed by a long time-interval, during which erosion has played an important part. The western end of the mountain, next to the Cape, consists of a granite knob 2,300 ft. high, known as Cape mountain, which rises so abruptly from Bering sea that there is not enough strand even for a foot-path. To the north the mountain slopes gently to the Arctic ocean, where there is a broad margin of low ground, formerly sand-spits, but now covered with tundra. These sand-spits are still forming, and enclose

Fig. 1. Sketch-Map of Alaska.

a series of lagoons along the coast, the largest one being known as Lopp lagoon. East of Tin City there is a broad tundra covered plateau extending to the York mountains, with an elevation of from 300 to 400 ft. above sea-level. This plateau is very much dissected by short valleys extending north and south, which, during the summer, are water-ways for the small streams. On the western side of this plateau, and against the granite mountain-mass, are three limestone terraces, which have the appearance of ancient beach-lines. The lower one is now very near the present beach, and no doubt the present narrow margin along the coast is, in places, of very recent formation. The upper terraces I am inclined to consider as the remnants of a monocline — or the west limb of an anticline, in which the erosion has progressed westward from a N-S axis of uplift. Six or eight miles east of these terraces, which are near the granite-lime contact, the strata dip in the opposite direction, and thus indicate the presence of the two limbs of an anticlinal fold.

The surface of the mountainous portions shows the effect of frost. The freezing and thawing process has gone on so long, and the outcropping rocks have been broken up to such an extent, that the surface is covered with loose fragments to a depth of from 5 to 20 ft. On

*Abstract from a paper entitled 'Geology and Mining of the Tin Deposits of Cape Prince of Wales, Alaska,' by Albert Hill Fay. Bulletin No. 17. American Institute of Mining Engineers.

the steep slopes this debris creeps so much that when float-ore is found, one can hardly even guess its point of origin. Except for some of the granite monoliths and an occasional limestone cliff, outcrops are scarce, making prospecting difficult.

The granite is coarse and light colored. The feldspar

There are four places where there is still some limestone on top of the granite, as shown in Fig. 3. Toward the top of Cape mountain, as well as near the Indian village, the limestone becomes more shaly, and even schistose in character.

Near the beach the contact between the limestone and granite is vertical, and about two miles farther north it dips east 80° . One-half mile farther to the north it dips 60° W. The slickensides show that some movement has taken place along this line. In addition to the main contact, there are occasional bodies of limestone which have been caught in the molten granite, and are now held as inclusions. It is alongside one of these that the best tin-ore has been found. This particular body of limestone is about 20 ft. thick.

At a number of places on Cape Mtn. a little tin float has been discovered, but not enough to be of importance. The deposits are small, as far as present developments show. Much of the granite carries traces of tin, and occasionally small stringers of cassiterite exist

crystals vary from a small fraction of an inch to 2 in. long. The hornblende crystals are few and small, and biotite is the prevailing dark mineral. The main body of granite has the appearance of a boss, on the top of which is a lime and shale cap. From this boss extend intrusions into the lime between the bedding-planes, and form sills which are nearly horizontal. There are also vertical dikes, from a few inches to 30 ft. thick, radiating from the central core and extending into the lime. These dikes appear to have the same texture as the granite along the main contact, and are probably contemporaneous with it. At one place I found a dike of rhyolite-porphry cut through the coarse granite. The contact between the two masses is sharp and showed no decomposition of either. At the contact the rhyolite and granite were actually fused together.

There were at least three periods of disturbance after the deposition of the limestone: 1. Eruption of the main granite mass. 2. Intrusion of rhyolite dikes. 3. Intrusion of basalt dikes.

After the limestone had been deposited came the great uplift, which formed the mountain and tilted the limestone beds. Then came a period of rest and the whole mass solidified. Following this was a long time interval, during which erosion played an important part. Then came the intrusion of rhyolite dikes, as mentioned above. I also found one basalt dike which cut through both the granite and lime, at the contact of the latter. No place was found where the basalt and rhyolite dikes cut each other; but, on account of the acidity of the rhyolite, it is probably the older of the two. The basic rocks have a lower freezing-point. It is not at all likely that the acid and basic dikes were intruded at the same time, for the two observed were only a few yards apart.

The limestone still retains its bedding-planes and is generally of fine grain and bluish color. In places near the contact with the granite it has become crystalline, while at others it is more silicious, with stringers of quartz between the bedding-planes; a large amount of the lime at the contact near the beach, as well as at the contact near the top of Cape mountain, has altered to wollastonite.

Fig. 2. Cape Mountain.

Fig. 3. Geological Map of Cape Mountain.

(Scale: $\frac{1}{4}$ in. = 1 mile)

along small fractures in it. In one case a stringer from 1 to 2 in. thick was found which was nearly vertical. This stringer passed through the granite, and also along the bedding-planes of the limestone, showing the tin to be later in origin than the limestone.

The cassiterite in the limestone was crystalline and exhibited good faces. Associated with it was quartz and limonite. The stringer of cassiterite in the granite was

more massive and had the appearance of a local enrichment. There was no marked line of contact; the centre was almost pure cassiterite, and passing from this to the granite the tin oxide seemed to give place to the biotite and feldspar until the normal granite was reached on either side. At one point of contact there is an iron selvage varying from a few inches to 4 ft. thick. The iron oxide (limonite) is quite pure and contained no tin. The tin at this place seems to be in the granite.

Along this granite-limestone contact there is an excellent example of the formation of tourmaline. All the necessary conditions are provided. The granite above the limestone lies almost horizontal, and must have provided, when in the molten and viscous state, practically a reverberatory furnace. This overlying mass, by reason of its weight, would retain emanating gases under pressure. All the constituents of tourmaline are at hand; lime in the limestone; iron, magnesium, aluminum, sodium, potassium, boron, and silicon in the granite. Boric fluoride is very readily absorbed by water (700 volumes of BF_3 to 1 of H_2O), and in this way it may have been supplied by the crystallizing granite. The tourmaline has formed on the lower side of the granite and exhibits well-developed crystals in quantity. As depth in the granite is gained, the amount of tourmaline diminishes. Below the tourmaline-granite, and resting immediately on the limestone, is a quantity of filling consisting largely of limonite and free quartz. This iron has undoubtedly been precipitated here as a sulphide, and is now the product of oxidation. This change has been wrought when climatic conditions were milder than now, for it is all in the frozen zone.

The presence of an occasional stringer of cassiterite in the granite, now in place, would indicate that the float tin-ore on the surface is simply a residual product of decomposition of the granite. It might be used as proof that there are still rich bodies of ore here; but it is more reasonable to regard the float as representing stringers and veinlets that have existed in bygone ages. Erosion has been great, and it is not an easy matter to say to what extent these deposits have been carried away. Placer tin is found in many places on the Seward Peninsula, and no doubt has the same origin.

On the whole, not enough work has been done to obtain much information concerning the size and continuance of the deposits. All that can be said now is that they are not large enough to pay to work. Some of these stringers may improve as depth is gained, but that remains to be seen.

The assay was usually made on 100 gm. of pulp of 60-mesh size. This pulp was carefully panned until most of the gangue had been washed off, leaving a concentrate of about 10 gm. containing cassiterite, with small amounts of pyrite, iron oxide, and tourmaline, together with the material clinging to them. This concentrate was then digested in nitro-hydrochloric acid for an hour, or longer, until all the soluble parts were dissolved, leaving most of the tin oxide reasonably clean. The residue, containing some quartz and tourmaline, was then thoroughly washed, dried, and weighed. A fire-assay on a number of these pannings gave an average of 70% metallic tin, while pure cassiterite contains 78 per cent.

By practice and careful work in the panning and acid-treatment, uniform results can be obtained. I made 300 tests on various samples in this manner and considered my final concentrate as 70% metallic tin. Though not absolutely correct, this method of assay is sufficiently accurate for testing rock, float, grab-samples, and prospectors' samples. Moreover, when at a distance from a

well-equipped laboratory, the best use has to be made of the tools and supplies that are available.

The charge for the fire-assay was made up as follows: 10 gm. of concentrate from ore was thoroughly mixed with 40 gm. of KCN (98%); 5 gm. KCN was placed in the bottom of the crucible, the charge then added, and covered with 5 gm. KCN. The time of fusion in gasoline furnace, from 15 to 25 min., gave a metallic tin button ready to be weighed. No analysis of the tin button was made to determine its purity.

Of 36 samples of granite, 13 contained a trace of tin, while 23 showed none. Those that had any tin whatever were nearest the contact, or, in other words, in the outer shell of the granite. Phillips and Louis, in describing a mine in New South Wales, report that "the tin-bearing portion of the granite is practically confined to a belt that forms the outer crust of the boss."[†] The portion of the vein-matter which could be taken as ore for treatment has a very low tin-content.

Down to the present time but little mining has been done, although there has been considerable prospecting by a half dozen concerns. A large part of this prospecting has been in the shape of open-cuts and costeaning trenches, in the endeavor to find the lode from which the float-ore has come. The surface of the ground consists of so much loose earth and boulders that it is difficult to obtain good results from open work. During the short summers, the ground will thaw only to a depth of from 3 to 4 ft.; and, below this, the digging is very hard. If the open-cut is on level ground, the melting ice and snow will flood it with water, so that it is necessary either to abandon the work, or to put in a pump, before bedrock can be reached.

Prospecting has been carried on continuously since 1902, the largest operations being those of the Bartels Tin Mining Co. The mining work consisted of a large number of open-cuts from 10 to 100 ft. long, many of which, however, did not reach bedrock; a number of short tunnels and two shafts—one 80 ft. and one 40 ft. deep. In two or three places some cassiterite was found in place. The surface improvements consist of two bunk-houses, two warehouses, a barn, a blacksmith's shop, and a power-house for electric drills. A Merrill 3-stamp mill was installed two years ago, comprising one 25-hp. Model gas-engine, a Blake crusher, a hydraulic classifier, and two Wilfley tables. The plant, which has a capacity of about one ton per hour, was operated during the summer of 1906, and a small shipment of concentrate was obtained. The next largest company operating is the U. S. Alaska Tin Mining Co., owning a number of claims on the north slope of Cape mountain. The underground work consists of one small and shallow shaft, and a tunnel about 250 ft. long. A 10-stamp mill has been installed. During the summer of 1906, Risley & Arrow-smith did some prospecting by the use of the calyx core-drills. Several holes were bored to a depth of from 50 to 100 ft. through lime to the granite contact, but I do not know what results were obtained. There are several minor prospect diggings, but they do not seem to be important or prominent.

The Gilday ventilating machine has been tried with great satisfaction at several mines in Australia. This ventilator consists of a belt-driven propeller shaft rotating in a tube. The vanes are helical surfaces, whose pitch is the length of the machine. The direction of flow of air is approximately axial, the diameter of the propeller is about 3 ft. The machine is run not to blow air into the mine but to suck the bad air out.

Faulting in the Red Cloud Mine.

Written for the MINING AND SCIENTIFIC PRESS
By H. W. TURNER.

The Red Cloud mine is situated in the Wood River district, Idaho, in the Deer Creek drainage, about seven miles due west of Hailey, the county seat of Blaine county.

This district has long been famous for its lead-silver

N. 50° W., and dips southwest at an average angle of 60°. The ore in the main vein came chiefly from the stopes to the south of the junction of the two veins.

Faulting has occurred on a small scale at numerous points in the mine, but the two movements that have affected the orebodies to the greatest extent are those herein described.

To illustrate the faulting, three sketches have been prepared. On these, only those features are shown that

are exposed in the mine workings. Thus, the main vein on Fig. 3 does not appear between points X and Y, because it is not exposed in No. 6 adit between these points. Likewise the hanging-wall vein on No. 6 level is not shown as uniting with the main vein, as the point is not proven by actual work on this level, although the two veins must really join on No. 6 level, as they are proven to do on No. 5 level above and No. 7 level below. An exception was made in case of the gouge seam shown on Fig. 3. This is exposed only at the west ends of No. 8 level, No. 9A level, and in No. 10 level. No. 9A level is 15 ft. above No. 9 level.

The fault with the greatest throw is that shown in Fig. 1. A block of

ground containing the upper levels of the mine has been shoved N. 20° W. a distance of about 240 ft. along a slip dipping northwesterly about 8°. This fault, or slip,

Fig. 1.

veins, the galena always carrying silver. The deposits are true veins occupying distinct fissures. Since the formation of the veins the rocks of the region have been extensively faulted, and the fact that a number of important mines are idle is due chiefly to the veins being lost, that is, cut off by faults. In certain cases, by judicious exploration, the veins have been recovered and production continued.

The Red Cloud deposits are in a calcareous shale, which has been shown by Waldemar Lindgren* to be of Carboniferous age. There are several veins on the property, but the two referred to in this paper are the only ones that have been developed extensively. The ore was an argenticiferous galena with some blende and pyrite, and according to Mr. Lindgren, also arsenopyrite.

Between 1880 and 1902, the Red Cloud mine produced ore of a gross value of \$815,802, as shown by the original records of the company in the possession of Judge Lyttleton Price, since deceased. Of this production, \$680,421 came almost entirely from the main, or Red Cloud, vein and nearly all the balance, or \$135,377, from the hanging-wall vein. The total product was 5,141 tons of lead (59.39%), 511,331 oz. silver (59.7 oz. per ton), and some gold, especially in the hanging-wall vein. Under the Kennelly lease, ore was extracted almost entirely from the stopes on the hanging-wall vein, 1,952 tons being shipped, containing 709 oz. gold, or 0.36 oz. per ton. The ore of this stope contained pyrite, and the gold is said to go with the pyrite.

The property was worked through adits for a vertical distance of 1,065 ft., but practically all the ore extracted came from above No. 9 level, which is only 706 ft. below the surface as measured from the mouth of No. 1 adit.

Two veins have produced practically all the ore. These are the main, or Red Cloud, vein and the hanging-wall vein. The former runs the entire length of the Red Cloud claim, and probably even farther south, toward the Red Elephant mine. It strikes about N. 23° W. true meridian, and dips westerly at a high angle, being in places nearly vertical. The hanging-wall vein branches off from the main vein to the northwest. It strikes about

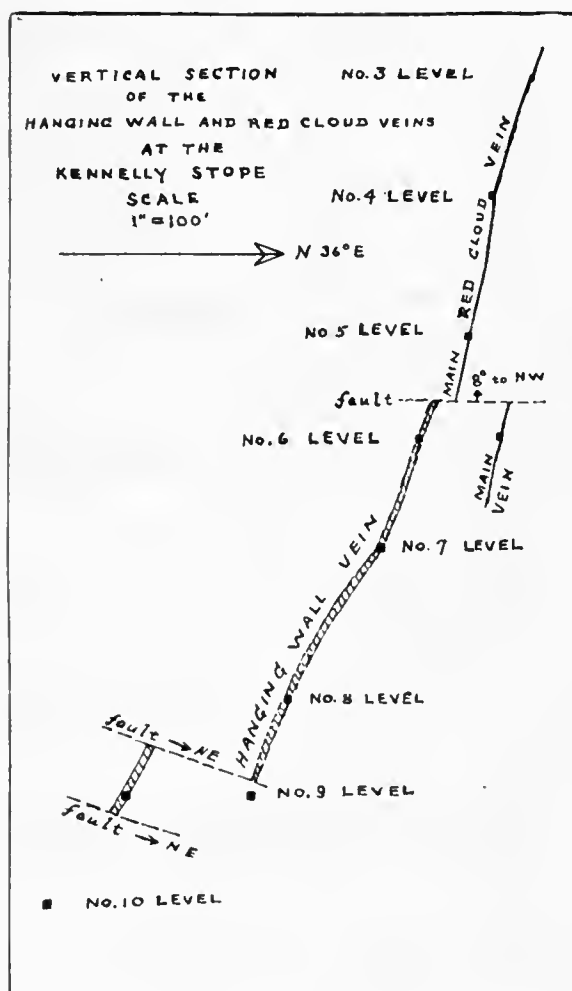

Fig. 2.

cuts both No. 5 and No. 6. levels, and is best seen at the south end of No. 5 level, where the ore was stoped to the slip. By following the old stopes, the fault sur-

*Twentieth annual report of the U. S. Geological Survey, p. 204.

face can be seen finely exposed for study, as it everywhere forms a roof to the stope.

The vein known as the hanging-wall vein branches off to the northwest from the main vein, and the point of its junction with the main vein is shown on Fig. 1, on No. 5 and No. 7 levels. In consequence of the faulting above described, the upper portion of this hanging-wall vein has been thrown northwesterly about 240 ft., which determines the throw on this fault-plane. On No. 6 level, in consequence of this movement, the hanging-wall vein appears twice, as shown in the horizontal projection of the workings in Fig. 3. The stope A, No. 6 level, represents the portion of the vein in the thrown block, and this stope is a continuation of the Kennelly orebody, although now 240 ft. to the northwest of its original position.

About the time the stopes of the main Red Cloud vein were exhausted the Kennelly ore-shoot on the hanging-wall vein was opened up, and the vein was followed down to No. 9A level, about 15 ft. above No. 9 level. Drifts on No. 9 level failed to find any vein or ore. Subsequently a cross-cut driven to the southwest encountered the vein, and it was finally demonstrated that the vein had been thrown 90 ft. to the southwest along a slip which inclined upward approximately 15° (see Fig. 2). The vein in this block was stoped to the fault, but in underhand stoping below No. 9 level it was found that the vein was again cut off by another slip, probably parallel to that above.

Considerable work was done on No. 10 level, and in the drift shown in cross-section on Fig. 2, on No. 10 level, some easterly dipping seams were found containing pyrite and zinc-blende, and one seam with lumps of argentiferous galena, which may represent drag ore. The hanging-wall vein itself was not, however, found on No. 10 level, although it is likely that a cross-cut run to the southwest from No. 10 would soon encounter the vein.

A gouge seam (see Fig. 3) on No. 8 and No. 9 levels cut off the vein to the north. This gouge seam has a nearly north strike and dips easterly about 68°. It represents a fault with a N-S trend on a different plane from those of the faults above described.

It is absolutely demonstrated in the Red Cloud mine that the veins are displaced by two marked monuments. One of these threw a block of ground above No. 6 level 240 ft. to the north, and another at about No. 9 level threw a block of ground 90 ft. to the southwest. It is also evident that this movement was repeated just below No. 9 level, the vein again being thrown, presumably in the same direction to the southwest.

At a point 1,065 ft. vertically below the mouth of No. 1 adit, a cross-cut 1,773 ft. long was run in an easterly direction. This cut a strong gouge seam containing calcite, and showing, by washing, some grains of sulphides.

This gouge seam has a course N. 10° E. and dips southwest at about 45°. It was known as the Yellow Dog vein, and was followed by a drift for 580 ft. From this drift another cross-cut was extended east a distance of 435 ft., when a second vein was encountered and a drift, known as the Kelly, was run on this vein for about 530 ft. At one point, a few tons of galena containing 100 oz. silver per ton, were extracted. The strike of the Kelly vein is about N. 45° W. and the dip southwest, from 33° to 60°.

From the Kelly drift, two cross-cuts were extended easterly each about 330 ft. in length, both of them cutting a third vein with a trend about N. 35° W. and a southwesterly dip. This third vein likewise contains grains of sulphides and vein-quartz but no commercial ore.

If we suppose that the block of ground containing the upper productive mine to have been shoved to the southwest on, say, the Yellow Dog vein, which is probably a great fault, the Kelly vein might correspond in position and trend to the hanging-wall vein and the third vein to the main or Red Cloud vein of the upper workings.

It has also been suggested that a large vein, apparently lean in ore, that exists on the surface to the east of the Red Cloud, represents one of these veins in depth. Undoubtedly more ore exists on the property, and as the expense of opening up in depth has already been incurred, it is a good gamble to make further explorations under the direction of an engineer conversant with the laws of faulting. Altogether, about 5,000 ft. of work was

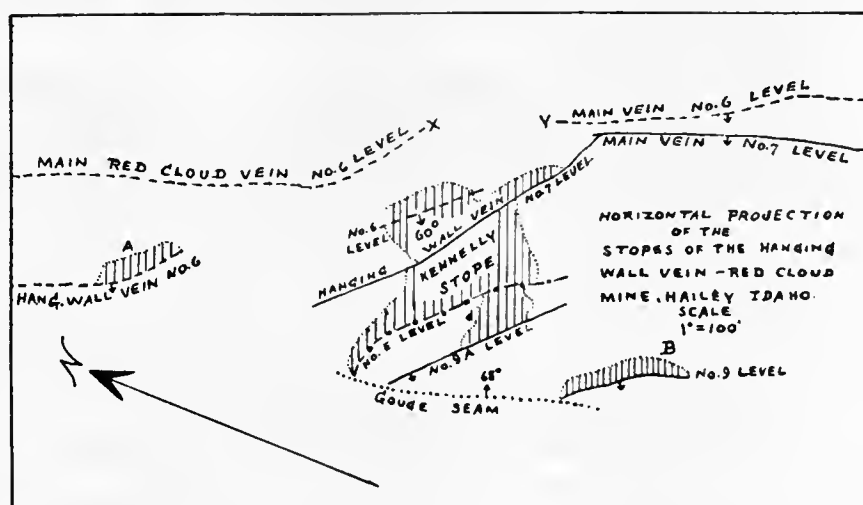

Fig. 3.

done on the lower adit-level without disclosing any ore-body.

Road Distances in Nevada.

During an automobile journey through the principal mining districts of Nevada, W. Q. Wright, Pacific Coast manager for the Wellman-Seaver-Morgan Co., ascertained the actual road distances between the prominent mining camps and towns of Nevada. The trip was made over the regular roads used by automobile stage-lines, and in order to measure each distance correctly an odometer was attached to Mr. Wright's machine. It will be interesting to those who have already traveled by stage in Nevada to note the discrepancies between the distances recorded herewith by Mr. Wright and the mileage as charged for by the motor stage companies:

Localities.	Distance Miles.
Reno to Wadsworth.....	35

Construction and Manipulation of a Gasoline Assay-Furnace.

Written for the MINING AND SCIENTIFIC PRESS
By WILTON E. DARROW.

While there are many fairly good combination gasoline assay-furnaces on the market, I am using a home-made one, which, in some respects, is superior to the manufactured furnaces that I have seen. I enclose a drawing and description of its construction, together with an account of the making of a control assay on sulphides as practiced at the Amador Reduction Works, at Amador, California.

The frame-work, or shell for the furnace, is made in two separate parts, marked *A* and *B*. The former is a rectangular box constructed of No. 16 sheet-steel, bound around the top with a strip of heavier metal to give it stiffness. This shell contains the melting-furnace and the fire-box, as well as the supports for the muffle.

This shell is approximately 18 by 30 in. square at the base by 11 in. in height. It contains a melting-chamber 10 by 10 in. and 9 in. deep. The waste products of combustion from this compartment pass through a 2-in. circular boss, set in a 4-in. circular flue, into the fire-box under the muffle. The top of the muffle is constructed with such an area that the muffle forms a complete cover, having about a $\frac{1}{2}$ -in. bearing all around, with the exception of two openings, $1\frac{1}{2}$ in. square, which communicate with a similar sized groove extending around the roof over the front of the muffle. This groove is constructed in the part of the shell marked *B*, which is 16 by 18 in. by 12 in. high.

In the construction of furnaces I use various compositions of material suitable to the purpose; some are refractory; some are for insulation; while others are simply to fill space in the shells. For the purpose of filling in the sides and corners of the lower compartment and the top of the muffle structure, good fine concrete is about the cheapest and best material to use.

For a top and cover of the furnace, and for insulating material between the fire-box lining and the concrete, I use the following mixture:

4 parts of old plumbago crucibles, crushed to 16 mesh.
2 " " asbestos packing.
1 " " fire-clay.
 $2\frac{1}{2}$ " " water.

The asbestos, clay, and plumbago should be well mixed by rubbing them through a coarse sieve before adding the water. This makes a spongy mass that is difficult to work into the desired shape, especially when making furnace-covers; but it is stronger and more durable than it would be if more water were used in its construction.

After the insulating material is in place, a mixture of 4 parts of old clay-crucibles crushed to pass 20 mesh and 1 part of fire-clay makes a good refractory lining for the fire-boxes and roof over the muffle; but it is better when given a thin finishing coat of a mixture composed of equal parts of fire-clay and old clay crucibles, crushed to pass 80 mesh, and made into a thick dough with water. I also use this mixture for constructing the bosses, and as a lining for my covers.

To construct covers I take a quantity of the plumbago mixture, then pat and rub it into the desired form on a piece of heavy paper spread over some smooth surface, where it can remain to dry and harden, after which I peel off the paper and apply a thin coating of the refractory luting, which protects the surface that is exposed to the fire from the fluxing action of the volatilized fluxes thrown off from the fusing assays. Covers made in this way are quite strong and durable; and if kept protected

from the fire, they will sometimes last for nearly a year. They are also excellent non-conductors of heat; and if one exercises a little care in their construction, they present a neat appearance, and can scarcely be distinguished from the commercial plumbago covers found in the market.

In operating the furnace, I use a couple of $1\frac{1}{4}$ -in. Cary burners, with 2-in. fire-bosses. For burners of this size F. W. Braun advises the use of bosses $2\frac{1}{2}$ in. diam., claiming that bosses of this size are necessary to keep the burners at a generating temperature; but I find that, if the discharge-flue from the fire-box is reduced to what I consider the proper size (2 in.), it burns the heads rapidly, though this can be largely remedied by facing the burners with a thin luting.

To recapitulate the important parts of the finished furnace: We have a fire-box 10 by 10 in. This will hold six 30-gm. crucibles; but I find that it works better with

only five, arranged in the form of a square, with one in the middle. The discharge from this compartment is through a 2-in. circular boss luted into a 4-in. circular flue, which enters the bottom of the fire-box. From the muffle fire-box the discharge is through two orifices placed close to the front of the muffle, one on each side. These admit the fire to the chamber above the muffle, the roof and walls of which are about $\frac{1}{2}$ in. away from the top and sides of the muffle itself. This construction throws the heat to the front of the muffle, where the cold air enters and thus equalizes the temperature so that it is under perfect control. Twenty-eight $1\frac{1}{4}$ -in. cupels can be inserted in the muffle, and if care is exercised in regulating the draft at the door, and if the heat from the burner is carefully adjusted, this number of buttons can be cupelled at once. All of them will show some feathers of litharge.

The ordinary inaccuracies and disagreements in assays can usually be traced to the four following causes:

1. Incomplete crushing and mixing of the sample.
2. Improper fluxing.
3. Bad control of the temperature during fusion.

4. Excessive temperature during cupellation. My method of preparing the samples for control assays is as follows: Starting with a large sample, I roll and quarter down in the usual way, until I have a sample of about 20 oz. remaining. This I crush to pass a 150-mesh sieve. I then mix this thoroughly by passing it several times through a 40-mesh sieve, rolling and mixing it on the cloth a few times between the siftings. The reason for so much care in sifting and rolling the crushed sample is that, when a high-grade concentrate is given, the first preliminary sifting on a fine sieve preparatory to crushing it throws the sample into two distinct grades of valuable material; besides the portion that is finally crushed to pass the fine sieve has a tendency to roll up in little balls on a sample-cloth, so that the sifting is necessary to get a perfect admixture of the first-crushed and last-crushed portions of the sample.

Our sample is then quartered and sealed in four packages, two going to the seller, one for assay, and the other is for the umpire in case of disagreement.

For the assay I take four $\frac{1}{2}$ A. T. charges of the ore. These I flux as follows:

	Grams.
Ore $\frac{1}{2}$ A. T., or.....	14.58
Litharge.....	70
Sodium bicarbonate.....	30
Borax.....	8
Silica.....	10
Nitre.....	22 to 25

This I charge into a 20-gram crucible, and cover with 10 grams of borax. Many assayers lay a great deal of stress on the exact quantity and kind of fluxes to be used in making up an assay charge; but I believe that on ordinary ores, any flux that yields a soft button of the right size, and carries an excess of litharge, with a fluid slag, will yield correct assays, if the other conditions are perfect. Of course there are exceptional cases, such as rich copper, or telluride ores, or ores that contain some element that carries all of the gold into the cupel (probably as an alloy similar to a case that came under my observation at the Golden Gate mine, of which I wrote in the MINING AND SCIENTIFIC PRESS under the title of 'Sampling and Assaying' in April last). Now, having the four assay-charges ready for fusion, and supposing that I have no other assay to make, I place an old slag-coated crucible in the middle, with the four control assays ranged around in the furnace, and start the gasoline fire, using from 15 to 20 lb. pressure. As soon as the burner is sufficiently heated to generate gas, I start the fire in the furnace, turning on a strong blast for about ten minutes; this starts the borax covers to melting. By this time the charges commence to simmer, and I reduce the supply of gasoline down to a quantity that will barely allow the fluxes to act on the ore; so that the action goes on without any boiling or spitting, and the charges slowly settle down in the crucibles in quiet fusion. This takes about half an hour. I now increase the supply of gasoline to render the crucibles hot and the slag fluid. Were the assays to be poured now, the results would be a little low, as some of the ore is left adhering to the sides of the crucibles, and the slag probably contains particles of ore that were not reduced before the lead was mostly precipitated. This warming will require probably about five minutes. I now turn on a quantity of gasoline in excess of the combustion-capacity of the furnace, owing to the restricted discharge-orifice, which is a 2-in. boss. This produces a reducing action and a slightly lower temperature. This action I allow for about ten minutes, when the surfaces of the assays and all exposed slag-surfaces will be covered with particles of lead that have been reduced from the excess litharge combining with the smoke from the unburned carbon in the gasoline. This shower of lead washes down all of the gold that was

left adhering to the sides of the crucibles, and, passing through the slag, it will collect nearly all of the gold that has a tendency to remain in the slag—usually attributed to 'slag absorption.' The supply of gasoline then being reduced to a point that gives complete combustion for about ten or fifteen minutes, the crucibles become thoroughly heated, and the lead is collected into one button. The assays are then poured. The empty slag-covered crucible will be found to contain a little shot of lead that was reduced from the adhering slag. If now there are no more fusions to be made, the old crucible makes an excellent plug to put into the discharge flue on the inside of the melting furnace, to confine the heat while the muffle furnace is in use. I can run both furnaces at the same time, if desirable; but find that my time is usually fully occupied in preparing other assays, and pounding and cleaning the buttons for cupellation.

A few years ago it was generally supposed that there was no appreciable loss in cupelling gold ores, and that the cupellations could be safely made with a high temperature in the muffle. This has, however, been disproved by many careful assayers. I have made many tests in this office in recent years, and find that there is a loss of about 2% of the gold if the cupellations are run at a high temperature.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of \$3 for each question. No assays are made.

A piece of decomposed granitic rock with blackish spots due to iron was sent by B. M. C., of Wonder, Oregon.

Specimens from Orleans, Cal., marked W. B., are: No. 1, Quartzite; No. 2, metamorphosed Diabase; No. 3, Diabase.

The rocks from Paris, Cal., marked E. F. E., are: No. 1, 2, and 5, Quartzite; No. 3, Granite Porphyry; No. 4, Rhyolite.

The two rock specimens from Seven Troughs, Nev., marked R. L. B., are: No. 1, Rhyolite; No. 2, altered Rhyolite.

The rocks from Homestead, Ore., marked F. E. P., are: No. 1, Serpentine and Chlorite with Pyrite; No. 2, Serpentine.

B. F. M., of Lander, Nev., sends: No. 1, Rhyolite; No. 2, weathered Rhyolite; No. 3, Andesite; No. 4, specular Hematite.

E. C. B., of Los Angeles, sends: No. 1, Galena, Chalcopyrite, Malachite, and Azurite; No. 2, earthy Hematite and Limonite.

The minerals received from J. L. H., of Isabelle, Cal., are: No. 1, Limonite; No. 2, Chalcopyrite and Bornite in quartz; No. 3, Magnetite and Pyrrhotite.

D. R. N., of Nelson, Nev., sends: No. 1, specular Hematite in quartz; No. 2, Fluorite; No. 3, Chrysotile Asbestos, Serpentine, and Quartz; No. 4, Epidote; No. 5, Calcite.

MOORE filter-baskets are used at the Waihi mill in New Zealand, not only for filtering cyanide solutions, but also for the purpose of merely thickening the slime-pulp before it is cyanided, there being a separate installation for that purpose.

The Roasting of Telluride Ores.

Contributed to the MINING AND SCIENTIFIC PRESS
By R. L. MACK and G. H. SCIBBD.*
With an Introduction by T. T. READ.

INTRODUCTION.

Telluride gold ores were first discovered in 1782, near Nagyag, in the historic goldfield of Transylvania, by a Hungarian peasant. From the first specimens Klaproth, sixteen years later, separated a new element, which he named tellurium. Similar ores were shortly afterward discovered near Offenbanya, also in Transylvania. Tellurides of various metals were discovered from time to time in different parts of the world, but the next discovery of importance from a mining standpoint was in 1871, when tellurides of gold and silver were found in Boulder county, Colorado. These were extensively exploited, and until the deposits at Cripple Creek in Teller county were uncovered in 1891, Boulder remained the chief locality for such ores in the United States. Soon afterward (in 1893) rich deposits of telluride gold ore were discovered at Kalgoorlie in Western Australia. Cripple Creek and Kalgoorlie entirely overshadow all the other telluride districts and are among the chief producers of gold, Cripple Creek furnishing \$15,500,000 of the \$58,000,000 of gold produced in the United States during 1905, while the production of Kalgoorlie was approximately one-quarter of the total production of \$56,000,000 credited to Australasia.

There are some twenty-six minerals that contain tellurium, but of these not all are recognized as well-established species. Five are tellurides of gold and silver, namely, calaverite, $(\text{AuAg})\text{Te}_2$ (Au 40%); sylvanite, $(\text{AuAg})\text{Te}_2$ (Au 25%); Krennerite, $(\text{AuAg})\text{Te}_2$ (Au 36%); petzite, $(\text{AuAg})_2\text{Te}$ (Au 26%); Hesseite, Ag_2Te (Ag 63%); and one, nagyagite, is a sulphotelluride of lead and gold (Au 7.5%). Recently Lenher has questioned whether the tellurides of gold and silver in nature are true compounds, since they will precipitate gold from its chloride solution². So many compounds, (galena, for example) have the power to reduce gold from its solutions that this argument does not seem entirely convincing. But the wide variation in composition of sylvanite and calaverite, which have the same chemical formula, lends color to the hypothesis that these minerals are essentially alloys of gold, silver, and tellurium, which by some unknown factor in the deposition of the ores, have been formed in approximately atomic proportions.

The difficulties presented in the metallurgical treatment of telluride ores were early recognized and have remained a subject of study to the present. The essential features of the problem are easily grasped. The telluride ores are all extremely brittle as well as extremely valuable; for this reason any ore-dressing method is entirely out of the question, as the losses in slime would be prohibitive. Direct smelting alone is also out of the question, as the ores do not contain lead or copper to serve as collectors of the precious metals, and, in the case of the Cripple Creek product, they carry so much alumina that they can only be slagged by mixing with other ore. In the case of the high-grade ores, which can bear the freight and treatment charges, it is possible to recover the precious metals in the dry way, by mixing them with leady ores in suitable proportions. In this way, there has grown up the custom of screening the ore at the mines; the lump ore is washed, sorted, and sent to the chlorination

or cyanide mills for treatment, the fine screening, which is much richer, ranging in value from forty to several hundred dollars per ton (due to the brittleness of the valuable mineral, and the tendency of the ore to break finer where it is most rich), is shipped to the smelters. Naturally the handling of large quantities of fine in the blast-furnace presents much difficulty and makes briquetting necessary. More recently it has been found by experiment that in the Huntington-Heberlein process for the desulphurization of lead ore, the Cripple Creek fine can be used instead of lime to keep the charge from fusing too easily, and with equal success. In this way a large percentage of fine is handled cheaply and conveniently.

But the cost of smelting makes some other method of treatment necessary for the ores of lower grade. It would be unprofitable to attempt to rehearse all the processes that have been tried and abandoned. Naturally, amalgamation was early tried on the oxidized ore of the upper portion of the veins, for although the tellurides themselves are not wetted by mercury and, consequently, are not amalgamable, yet in the oxidized portion of the veins the mineral has generally lost its tellurium, leaving the gold in a spongy brownish form, known as 'mustard' gold. But this gold is not in a state suitable for amalgamation, partly because of its spongy nature, and partly because its surface is not clean and bright, allowing ready wetting by the mercury. Leibius decided that the 'rustiness' was due to a coating of iron oxide on the gold; and other writers have ascribed it to a coating of the tellurite of iron (a mineral described by Knight³ which has no mineralogical name, and is doubtful as a mineralogical species). It seems most probable that it is chiefly due to the physical state of the gold, as gold precipitated from solution in a spongy form is not readily wetted by mercury, a fact which Henry Louis has ascribed to the existence of gold in a dimorphous form.

Of the various wet methods, only two, chlorination and cyanidation, have met with any degree of success. Cyanidation was early tried on the oxidized ore, but because the process had not then reached as advanced a state of development as at present, the results were not usually successful. Many difficulties were encountered, of which probably the chief were the mechanical ones of leaching the finely ground ore and filtering the solutions. The unoxidized ore is not amenable to cyanidation, as the telluride is not readily attacked by cyanide solution. The treatment of the ores by chlorination involves a preliminary 'dead' or 'sweet' roast to eliminate all reducing substances, which would otherwise consume chlorine. The advantages and disadvantages of the chlorination process for Cripple Creek ore have been discussed at length by Greenawalt and Argall in a series of papers published in Vol. 78 of *The Engineering and Mining Journal*. Until recently the chlorination process has been regarded with more favor than the cyanide process. But since the chlorination process costs for extraction approximately \$3.50 per ton on average ores, and only gives a yield of 95% of the gold and none of the silver contained (which gives a tailing richer than \$1 per ton on average ores), there has naturally arisen a demand for a cheaper process which shall give a greater extraction. Temporarily the chlorination process is supplemented by concentrating the tailing from the chlorination barrels on Wiltley tables, the concentrate being shipped to the smelters, while the tailing from the tables is cyanided by decantation.

The application of the cyanide process to the unoxi-

dized ores has been chiefly worked out by Australian metallurgists. Development has progressed along three principal lines, namely, (1) fine grinding, roasting in Merton or Edwards furnaces, and cyanidation by leaching, decantation, filter-pressing, or combinations of these; (2) rather coarse grinding, roasting, amalgamation in pans or on plates, and cyaniding the tailing; (3) concentration on tables to extract the sulphides (which are roasted and cyanided), followed by extraction of the gold from the unroasted tailing by means of cyanogen bromide. The difficulty in roasting and cyaniding direct is that the telluride mineral exists in the ore in rather coarse particles, which melt at the beginning of the roast into globules that afterward become, by the loss of their tellurium, pellets of gold, which are not entirely dissolved during any reasonable length or exposure to the action of the cyanide solution. The West Australian ore also contains some free gold, which adds to this difficulty. This has been taken advantage of in the process of Sutherland and Marriner, who advocate crushing rather coarsely, conducting the roast in such a manner as to yield a maximum of the gold pellets, and then amalgamating these in pans and on plates. The chief objection to this method is the difficulty of preventing the escape of mercury into the tailing from the plates. The third method, known as the Sulman-Teed process, in which the values are extracted directly from the unroasted ore by the use of cyanogen bromide, is entirely successful, but on West Australian ores shows no advantage in cheapened cost or greater extraction. It seems highly probable, however, that if properly modified to meet the slightly different features of Cripple Creek ores, it could be applied to them at a less cost and with more satisfactory results than either of the other processes.

The roasting of telluride ores preparatory to cyanidation presents several unusual features. The roast is ordinarily controlled by determining the elimination of the sulphur. But the sulphur is essentially not concerned in the roasting, as the amount of sulphides present in these ores would not ordinarily affect their cyanidation, the real problem being to free the gold from tellurium in order that it may become soluble in the cyanide solution. Once begun, however, the combustion of the sulphur must be carried to completion to break up the sulphates at first formed. It is arbitrarily assumed that a roast which is satisfactory from the standpoint of the sulphur, has also satisfactorily eliminated the tellurium, but direct proof of this is entirely lacking. It is not even known whether the tellurium is driven out in the roasting of these ores. Richard Pearce⁴ has shown from experiments that the tellurium may be almost entirely changed to TeO_2 and retained in the ore, probably as a tellurite, but that the presence of pyrite causes it to be driven off to a much greater extent. He also found that tellurium may be sublimed directly in the roasting furnace, as crystals of it have been found to occur there. There remains, therefore, considerable doubt as to the behavior of the tellurium beyond that the gold is freed of it in a properly conducted roast.

In freeing the gold of tellurium, certain losses are known to occur. These may be due to (1) a mechanical loss in dusting from the driving out of the moisture and gases of the ore, (2) a mechanical loss from the driving off of tellurium from the gold, (3) a loss by actual volatilization of the gold. F. C. Smith⁵ found an average loss of 11.45% of their gold contents on roasting various samples of the Potsdam ores of the Black Hills for one hour. The method of conducting the roast is not described. It is well known that no such losses as these

ordinarily occur in roasting Cripple Creek ores. It seemed wise, therefore, to undertake to investigate what the losses in roasting actually are, and how they are affected by various physical conditions.

EXPERIMENTS IN THE ROASTING OF TELLURIDE ORES.

The object of this investigation was to find:

1. The effect of the size to which the ore is crushed before roasting upon the degree of desulphurization attainable and upon the loss of gold.
2. The effect of the temperature at which the roast is conducted upon the desulphurization and loss of gold.
3. The amount of gold lost during roasting.
4. The relative distribution of the gold in the various sizes of crushed ore.

The ore upon which the tests were made was a lot of about 300 lb. obtained from the Portland mine, which is situated on Battle Mtn., in the Cripple Creek district, Colorado. It is representative of the ore of that mine, as described on page 442 of Professional Paper No. 54, issued by the U. S. Geological Survey on the 'Geology and Gold Deposits of the Cripple Creek District.'

"All the unoxidized ores are alike in owing their value to the presence of a telluride of gold which seems to be almost invariably calaverite, although the occurrence of sylvanite has been reported by Rickard. This telluride is rarely found in well formed crystals and is frequently present in particles so minute as to be invisible to the naked eye. The ore most typical of this mine is that occurring in breccia, which is fine grained and gray, made up of barely recognizable fragments of phonolite and andesite and locally blocks of granite sometimes as much as from one to six feet in diameter. Finely disseminated through it are much finely divided pyrite and considerable scattered carbonate. The calaverite occurs in very narrow fissures or joints in this breccia, associated with crystalline films of dolomite, with sometimes a little silica and fluorite. In most cases the ore shows very little calaverite to the naked eye. The value of the ore appears to lie wholly within these narrow joints. The fine pyrite impregnating the breccia is not known to be auriferous."

The following table shows a comparison between analyses made by the U. S. Geological Survey on Portland ore and that made by us. The Survey analysis was made on "Normal ore from the Portland mine, largely from breccia, country rock, and slightly oxidized."⁶ The object in making this analysis was to find out if any great variation existed between our lot of ore and that experimented on by the Survey:

	U. S. G. S.		C. C.
SiO_2	54.91	54.68	53.3
Al_2O_3	17.80	17.87	16.8
FeO.....	4.80	5.30	4.14
MgO.....	0.36	0.20	Not determined
CaO.....	2.04	2.65	3.08
Alk.....	12.00	12.00	Not determined
MnO ₂	0.66	0.94	"
S.....	2.49	2.25	3.08

The ore upon which our tests were made was taken from a hopper just before going to the roasters at the Portland mill. It had been broken by Blake crushers, followed by rolls, and all had passed through a 14-mesh screen. The following table shows the results of a screening test and the percentage of gold in the various sizes. A comparison is also shown between the screens used for this test and those recommended by the Institution of Mining and Metallurgy. The dimensions of the wires and apertures of the screens were obtained by means of a microscope having a micrometer eye-piece, the results being the average of a large number of readings. The nest of screens used, of the meshes shown, were of the usual 8-inch heavy tin-plate, brass gauze, as obtained from the Denver Fire Clay Company:

⁴ *Proc. Colo. Sci. Soc.* Vol. V, p. 144 (1895).

Through 150				1.58	25.38	21.03	3.93

The screening test was performed by placing 100 grams of the crushed ore upon the coarsest of the nested screens and replacing the cover. The nest of screens was then inclined at an angle of 30° and the ore made to pass across the screens by jarring them with a heavy spatula. When it had all been brought to the lower side, the screens were again tilted to bring this side uppermost, and the ore made to pass back again. This process was continued until it was judged that no more material was passing through. The top screen was then removed, the material retained on it weighed, and the jarring process continued some time longer on the next screen. In this way the finest screens received, as is necessary, more jarring, and the comparative uniformity of the results thus obtained indicate the accuracy of this method of performing the screening assay. Five trials are recorded:

The amounts retained on the various screens were then sampled, crushed on a bucking board to pass 100 mesh, and assayed, the following charge being used:

One-half assay-ton† of ore; 1 of lead flux; $\frac{1}{2}$ of Na_2CO_3 ; and 1 assay-ton of PbO . Then a borax cover.

The lead flux was composed of 16 parts, K_2CO_3 ; 16 of Na_2CO_3 ; 8 of flour; and 4 of borax.

The sulphur in each size was also determined, the following method being used: Treat one gram of ore with $\frac{1}{2}$ gm. KClO_3 and 7 cc. HNO_3 conc., adding 3 cc. of the acid first and letting this boil to fumes of NO_2 and then adding 1 cc. at a time, the final volume of the acid present being about 2 cc. When the flask was removed from the heat, diluted with 50 cc. H_2O and an excess of Na_2CO_3 added to precipitate Fe, etc. The solution was then boiled 30 to 60 min., the bulk being kept constant. It was then filtered and the precipitate washed until it was free from all traces of H_2SO_4 . The filtrate thus obtained was acidified with HCl and boiled until all the CO_2 was expelled, when the SO_3 was precipitated with BaCl_2 and weighed as BaSO_4 after ignition. As is seen from the above table, a slight increase of gold is found in the fine. This is due to the fact that the gold minerals occur in the cleavage planes of the ore. When broken, it yields along the cleavage, since this affords lines of weakness, thus exposing the tellurides, which are scraped off and become concentrated in the fine. This difference is more marked between the lump ore and the fine screening than is the case with such fine ore as was used in the above tests, because this ore already consists of fine material and

hence the opportunity for concentration is not so great. The increase of sulphur in the fine as shown by the above table is due to the fact that the pyrite disseminated in the ore being brittle is easily broken and worn away, and hence concentrates in the fine material.

ROASTING.—The necessity for the roasting of tellurides preparatory to cyaniding is due to the insolubility of tellurides in cyanide solutions. Crooks says: "Tellurium not only refuses to form a telluro-cyanide when fused with potassium cyanide, but takes the place of the cyanogen therein, forming potassium telluride, which is speedily decomposed by the action of the air, into potash and metallic tellurium."

There is no action between the cyanogen radical and tellurium, but the alkali in presence of oxygen invariably dissolves some of the metal, forming a solution which has a reducing action. When a telluride ore is roasted it leaves a residue containing TeO_2 , and this oxide is very soluble in KOH , forming a tellurite, which also acts as a reducing agent and absorbs oxygen from the solution. The same change takes place with KCN with an evolution of HCN . Roasted tellurides are, however, capable of being treated, and the gold extracted with good results.⁸ It is said that when an ore has been roasted sufficiently to be ready for chlorination it is also in a suitable condition for cyaniding; the reverse, however, is not always true. The aim of roasting telluride ores before cyaniding is to leave the ore in such a condition that there shall be no deoxidizing agents or cyanicides present. The effect of cyanicides is simply to use up the cyanide in the solution, while the deoxidizing agents prevent the dissolution of the gold in a reasonable time. The objects of roasting are:⁹ 1. To convert the base metals into insoluble compounds, or into compounds which, if soluble, do not act as reducing agents in the solution. 2. To form soluble compounds which do not decompose the KCN solution. 3. To liberate all the particles of gold and silver from any encasing matter. As it is not practicable to determine tellurium in the ordinary operations of the works, it is assumed that when the sulphur is well burned off that the tellurium is also burned off, or volatilized. This assumed close relation between the actions of sulphur and tellurium does not seem to hold exactly for all ranges of temperature. The sulphur in telluride ores occurs almost entirely as FeS_2 (iron pyrite). The process of burning off the tellurium consists of four distinct changes, as follows:

1. $\text{FeS}_2 = \text{FeS} + \text{S}$. One atom of the S is rather loosely held and is driven off at a rather low temperature—350° C (598° F).

2. $3\text{FeS} + 11\text{O} = \text{Fe}_2\text{O}_3 + \text{FeSO}_4 + 2\text{SO}_2$.¹⁰

The last reaction and the one most difficult to effect occurs at a temperature of about 695° C (1,283° F) when the sulphate is decomposed as follows:

3. $2\text{FeSO}_4 = \text{Fe}_2\text{O}_3 + \text{SO}_3 + \text{SO}_2$.¹¹

If the temperature at the completion of the roast is not around 700° C (1,290° F), FeSO_4 will be left in the ore, which dissolves cyanide and robs the solution of its free oxygen. On the other hand, the temperature must be low at the start of the roast or some of the base metals and tellurides may fuse and form (with the iron pyrite) a matte, which encases the gold, destroys the effects of previous fine grinding, and prevents the solution from dissolving the gold in a reasonable length of time.

A telluride ore crushed to go through a 14-mesh screen and containing 3 to 4% sulphur, if heated to a temperature around 1,095° C or 2,000° F, will be highly fritted.

¹¹ Hoffman: 'Metallurgy of Lead.'

†An assay-ton equals 20,166 oz. Troy.

This is shown from tests made by us, the temperatures being determined by the Fery pyrometer (Test No. 3). The same test also showed that the temperature best adapted for driving off sulphur is obtained by slowly heating the ore, with an excess of air, up to 830° C (1,526° F) and also that the sulphur may (in the case of Cripple Creek tellurides) be properly burned off at a temperature considerably below the fritting point of the ore.

If a high-grade coarsely crushed telluride is roasted, a condition may result known as shotting of the gold. It is due to the fact that the telluride melts at a comparatively low temperature and forms globules, which, on roasting, lose their tellurium, leaving the gold at the end of the roast in the form of shot, which are very slowly attacked by cyanide solutions. In order to determine the temperature at which shotting occurs, the following tests were made: A copper Constantin thermo-couple was connected to a galvanometer. The junction was arranged so as to lie flat on a piece of mica, under which a wire gauze served to distribute the heat evenly. Small pieces of calaverite, the most common telluride of the Cripple Creek district,¹² were placed beside the junction and a Bunsen burner used to heat them both. By noting when the tellurium melted down, as was easily detected by the eye, the temperature required to effect this was read directly on the galvanometer. A series of these readings showed conclusively that the temperature required to melt this particular telluride is about 365° C (689 F). If calaverite is further heated the tellurium is volatilized and burns with a green flame. By the use of practically the same apparatus as in the previous test, it was found that the point at which tellurium begins to be driven off is 550° to 575° C (1,031° to 1,057° F) and that the tellurium continues to be volatilized until the melting point of gold is reached (1,064° C to 1,947° F). It was found that the smaller the amount of tellurium with the gold, the higher the temperature required to drive it off. This is due to the fact that the last part of the tellurium is mechanically held in the globules of gold. However, as would be expected, the amount of tellurium left with the gold after the sulphur has been well eliminated, varies directly as the fineness of the crushing, being least with fine crushing.

(TO BE CONTINUED.)

SULPHURIC ACID FROM PYRITE.—In Great Britain sulphuric acid is made almost entirely from pyrites imported from Spain. Brimstone is used less and less every year and is reserved for the manufacture of acid for very special purposes. Sulphureted hydrogen, derived from the waste gases of sulphate of ammonia manufacture, has been applied extensively during recent years, and is an important source of supply of sulphur. British producers of sulphuric acid complain of the increasing difficulty in obtaining pyrite free from, or low in, arsenic, and several new plants for de-arsenication have had to be erected. The process now used by the United Alkali Co. for removing arsenic produces it as pure arsenious acid instead of the mixed mud of arsenious sulphide, as formerly. It is interesting to note that in the midland counties of England 'coal brasses' from the coal mines are used as a source of sulphur at the sulphuric acid works.—*The Chemical Engineer.*

MERCHANT TONNAGE OF THE WORLD.—According to statistics just published by *Lloyd's Register*, the merchant fleets of the globe now total 39,138,000 tons, or nearly 2,000,000 more than a year ago. Of this huge total no less than 33,969,000 tons represent steam shipping, and 17,001,000 tons of it is under the British flag.

¹²Professional Paper No. 54, U. S. Geol. Sur., p. 442.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

Where a miner had himself tunneled out the room and after part of the roof had fallen, had himself placed a bar at such place in a workman-like manner, sufficient to render the roof reasonably safe, such miner had the option to do his own timbering for pay, or to have the company's timberman do the work. It appeared also that the foreman had regularly inspected the room, and had found it free from signs of weakness on the day before the accident. Under such circumstances, it was held that the company was not negligent and not liable for the death of the miner caused by falling of the roof.

Brunson v. Southwestern Co., (Ind. Ter.) 104 Southwestern, 593, Sept., '07.

A lessee was not entitled to take advantage of a condition in the lease where it provided that royalty should not be collected where the production or shipping of coal was prevented by the destruction of breakers, where it was shown that one breaker was destroyed by fire, but the remaining breakers were sufficient to prevent interruption to the mining and shipping of the coal.

Everhart v. Lehigh Coal Co., (Pa.) 67 Atl. 618, May, '07.

As between two lessees of different portions of a mine, each must know that the only use to which the ground can be put is mining; and the landlord is not liable for the willful or negligent acts of the tenant of the upper level and was not required to take active measures to prevent the caving of the ground of the upper level to the injury of the tenant and lessee of the lower level. In such case, it is the duty of the tenant or lessee to require from the mine owner such reasonable stipulations as will protect him. In order to hold the mine owner liable in such case, it must appear that he made the lease to the lessee of the upper level after leasing the lower, and that the actual situation was then such that no other result could have followed from working the upper ground but material injury to the lower, and that such state of affairs was known to the mine owner when the upper ground was leased.

Peterson v. Bullion-Beck Co., (Utah) 91 Pac. 1095, Sept. '07.

The law does not presume, merely because one tract of ground is above the other, that the working of the upper will injure the lower; the lessee of the lower level is bound to protect his own rights in making a contract against the operations of one above him, if the situation is such as to require it, rather than to rely upon a supposed duty of the lessor or mine owner, to protect him at all hazards.

Peterson v. Bullion-Beck Co., (Utah) 91 Pac. 1095, Sept. '07.

Where, in an action under the statute providing that an adverse action must be commenced within 30 days after the filing of the adverse claim, the complaint was filed within the 30 days, and the filing by the defendant of a general demurrer after the 30 days was held to be a waiver of the issuance of summons under the Practice Code providing that, after the filing of the complaint, a defendant may appear, whether the summons has been issued, etc., and that this had the effect of the issuance of summons on the day the complaint was filed, and conferred on the court jurisdiction of the subject matter and the parties.

Harris v. Helena Min. Co., (Nev.) 92 Pac. 1, Oct. '07.

Where a miner was burned in an explosion because the owner failed to comply with a statutory requirement, he was entitled to recover for permanent disability and inability to earn a living, for his pain and suffering, and also for the humiliation of being handicapped through life by distorted features and body.

Bolen-Darnall Co. v. Williams, (Ind. Ter.) 104 Southwestern 867, Sept. '07.

Lifting Magnets.

Wherever pig iron, metal plates, tubes, rails, beams, scrap or heavy castings of iron or steel are handled, lifting magnets can be advantageously employed. The time saved due to the fact that hoisting tackle need not be adjusted to the object to be raised is of itself often sufficient to justify the purchase of a lifting magnet. For handling pig iron, scrap, and similar material a further advantage is found in the fact that the objects to be moved need not be piled beforehand. All that is necessary in work of this sort is to lower the magnet onto the pigs or scrap, switch on the current—and lift. In foundries, blast-furnaces, and rolling mills magnets are useful for lifting and transporting metal too hot to be touched with the hand.

Castings which, because of their shape or because of une-

have been picked up from a wooden car or from the ground.

At the tests conducted at the Carnegie Steel Co.'s Works a 50-in. Cutler-Hammer magnet lifted from the ground 32 sand-cast manganese iron pigs averaging 65 lb. each in weight—a total lift of 2,080 lb. During the same test this magnet readily picked up a steel 'skull' weighing 5,500 lb., this in spite of the fact that the surface presented to the magnet was very uneven and extremely dirty, being almost covered with slag at the point where magnetic contact was made. Under fair average conditions a 50-in. magnet should handle from 1,000 to 3,000 lb. of material at a time, but this may fall to 500 lb. under adverse conditions, or rise to 10,000 lb., or even 20,000 lb., under conditions extremely favorable.

Every prospective purchaser of a lifting magnet naturally wants to know the amount of current consumed, so as to intelligently calculate the saving that may be reasonably

10-Inch Magnet Lifting 800 Lb.

A Ton at a Time.

qual distribution of weight, require careful adjustment of hoisting tackle, and finished parts which would be liable to be chafed with chains, are examples of objects which can be more conveniently handled with lifting magnets than in any other way. Armor plate and thin sheets of iron or steel used in the manufacture of pressed steel or iron ware, ear wheels, and a multitude of other finished or raw products forming part of the metal industry are all capable of being expeditiously and economically handled with lifting magnets.

Perhaps the question most frequently asked concerning a lifting magnet is: How much will it lift? This depends on the nature of material handled. Given a solid mass of steel or iron, a 50-in. Cutler-Hammer magnet will lift as much as 20,000 lb. Under adverse conditions the lifting capacity of the same magnet might drop to 1,000 lb. or less. In the test at the works of the Youngstown Sheet & Tube Co. adverse conditions were present, owing to the fact that the pig iron had to be lifted from a steel gondola. The average lift (755 lb.) would have been greater if the pigs could

expected in handling material with this labor-saving device. The following figures, obtained during the test of a 50-in. Cutler-Hammer magnet at the plant of the Youngstown Sheet & Tube Co., throw light on this point:

Total weight of pig iron unloaded from steel gondola.....	109,350 lb.
Weight of average lift (including 'lean' lifts when cleaning up car).....	785 lb.
Trips required to empty gondola.....	139
Current on magnet.....	1 hr. 15 min.
Current off magnet.....	50 min.
Time consumed in unloading gondola.....	2 hr. 5 min.
Current required to energize magnet.....	30 amperes at 220 volts.

From the foregoing figures the cost of operation is easily calculated, assuming cost of current to be 3 cents per kilowatt hour, which is much in excess of actual cost of current in large industrial plants. Thirty amperes at 220 volts corresponds to a power consumption of 6,600 watts, which was required for 1 hr. and 15 min. This gives a total power consumption of 8.25 kw. hr., which at 3 cents per kw. hr. gives a total of a little less than 25 cents—cost of current for energizing magnet during the period required to unload 54 tons of pig iron.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

ROCK-DRILL AND OTHER PERCUSSION TOOL.—No. 870,658; Thomas Warsop, Coniston, England.

The combination in a percussion tool, of a petrol motor, a shaft driven by said motor, a second shaft geared to the first shaft, a cam on said second shaft, a tool carrying spindle, a pair of bell crank levers pivoted intermediate their ends, the outer ends of said bell crank levers being connected to said spindle, a cam roller mounted between the inner ends of said bell crank levers and in the path of said cam, whereby said cam will move said spindle in one direction, and a spring for moving the spindle in the other direction.

MINE-CAR.—No. 870,542; Eugene C. Callahan and Frank L. Callahan, Terre Haute, Indiana.

In a mine-car the combination of a metallic frame constructed of channel and angle iron parts and provided with open clips adapted to engage the standards of the sideboards, draw-bars at each end, axle sleeves, axles and traction wheels, with a bed consisting of hopper-like sideboards, provided with standards adapted to brace the sides and to engage clips provided upon the sides of the metallic frame, a rear end-gate attached to the side-boards, an automatic front end-gate attached to the front ends of the frame and bed, by means of a system of operating levers, a system of levers attached, respectively, to the sides of the car and the front end-gate, and adapted to operate the front end-gate, all substantially as described and shown and for the purpose set forth.

PERCUSSION-DRILL.—No. 871,350; Bradford H. Locke, New York, New York.

In a machine of the character described, the combination of a shell or casing, an internally grooved cylinder mounted to rotate therein, an end thrust ball bearing at the forward end of said cylinder, a lateral ball bearing at the rear end of said cylinder, an adjustable bearing at the rear end of said cylinder to prevent excessive movement from the forward

thrust bearing, a spirally grooved piston within the cylinder, a ball coupler engaging the piston and the cylinder, a piston shaft and a spring to drive the piston shaft in one direction.

ELECTRIC FURNACE AND METHOD.—No. 871,273; Paul L. T. Héroult, La Praz, France.

An electric furnace having a pair of electrodes, a conductor adapted to form a part of the path of the current between said electrodes, and means for shifting said conductor to vary the length of the part of the path formed thereby.

PROCESS OF LEACHING ORES.—No. 871,300; Alfred Schwarz, New York, New York.

The method of leaching ores consisting in causing the ore to descend by gravity through a series of hoppers submerged in a quiescent solvent, and introducing air into said solvent in the presence of the falling stream of ore.

ROCK-DRILL.—No. 871,594; Edward N. Jones, Victor, Colorado.

A rock-drill comprising a main cylinder, a hammer piston therein, a drill chuck in which the drilling tool is mounted to slide and to turn with the said chuck, a pawl on the said drill chuck, a loosely mounted ratchet wheel engaged by the said pawl, an auxiliary cylinder connected by an admission port and by an exhaust port with the said main cylinder, an auxiliary piston in the said auxiliary cylinder, and means for connecting the piston with the said ratchet wheel to turn the latter

Editorial.

A GOOD INDICATION of the prosperity of the workingman in this country is afforded by the amount of money transmitted through the post-office from New York to Europe. In the two weeks ending on December 18, the New York post-office issued no less than 319,754 money orders, calling for \$5,366,771, an increase of 66,286 orders and \$1,156,698 as compared to the same period last year. Most of these orders represent Christmas remittances from immigrants to their people in the home country.

UNDER 'DISCUSSION' we publish a letter voicing some of the grievances of the working miner. To those that want to be fair in their dealings with employees, this letter will prove suggestive. While not endorsing all the statements made by the writer of that letter, it will serve to present one cause of the industrial troubles so hurtful to the progress of mining. The "inhumanity of man to man" makes many fight, as well as "mourn."

TUBE-MILLS and the lining of them with a resistant material are subjects of special interest to cyanide experts. The little controversy regarding the invention of the El Oro lining illustrates the fact that a good idea is apt to occur to more than one man at about the same time. We described this lining in our issue of October 12, on the basis of notes kindly communicated by Mr. Alfred F. Main, assistant manager to the El Oro Mining & Railway Company. It appears to be an excellent invention, whoever may be the inventor.

IN THIS ISSUE we publish the second portion of the article describing the results obtained in the experimental roasting of telluride ores. There is little information extant on this subject, and this fact alone would render the article valuable. Those who are engaged in the cyanidation of telluride ores, whether at Cripple Creek or Kalgoorlie, will be grateful to Messrs. R. L. Mack and G. H. Seibold, and to Mr. Thomas T. Read, also, for giving so many suggestive data concerning this branch of metallurgy.

THE SCANDAL associated with the failure of the California Safe Deposit Company has brought into prominence the names of the two Treadwell brothers, who were directors of the defunct institution and contributed to the catastrophe by their borrowings. These are the men who discovered the Alaska-Treadwell mine and sold it for something over a million dollars. James Treadwell was a carpenter and in his statement explaining the transactions that ended so disastrously he illustrates the danger of a gold miner dabbling in matters outside of his experience. It is pathetic to read of the attempt made by these once fortunate gold miners to make money out of

a coal mining enterprise based on deposits of "lignite of fair quality." The moral is again: "Shoemaker stick to your last."

A LITTLE PERSPECTIVE often aids mental vision, therefore the backward glance at the history of gold and silver, as given by Mr. James W. Malcolmson, will be appreciated. The relation of gold production to commercial activity has been brought to the front of late, but the problem remains sufficiently unsolved to be a subject for dispute. Undoubtedly the gold production of the world will begin to lessen soon, but when? Goldfields become exhausted, but new ones are discovered, and despite the skimming of the cream from off the natural concentrations of gold-bearing alluvium, the improvements in the economical treatment of ore are continually adding to the tonnage to be worked at a profit, and when the land has been exploited to a finish, is there not the ocean, which on the basis of 5 milligrams per ton of sea-water, contains something like 10,000,000 tons of gold. But the miner need not fear this source of supply, for the gold occurs in such a minute proportion as to defy any method of extraction as yet imagined.

The Goldfield Consolidated Report.

THE ANNUAL REPORT of the Goldfield Consolidated Mines Company, for the year ending on October 31, has been awaited with much interest because circumstances have united in placing this company in a prominent place among the mining enterprises of America. Ore of unusual richness, a picturesque setting, speculation in the stock, and labor troubles have been among the factors contributing to a dangerous prominence. We say dangerous, because pre-eminence of any sort invites the searchlight of criticism. Such criticism should be considerate, for the early development of the group of mines now consolidated was lacking both in system and economy, the leasing of the rich ground made direct control difficult, and the dependence upon a precarious ore market interfered with regularity of production. Nevertheless, any undertaking that appeals for public support must be amenable to public opinion and it is the particular province of journalism to guide such opinion. The consolidation at Goldfield was organized on November 13, 1906, with the Mohawk, Red Top, and Jumbo mines; and it was not until March 1, 1907, that the Combination was acquired. Therefore the annual report does not cover a full year. Owing to various strikes, 99 days of work were lost. At the time of acquiring control all these mines, except the Combination, were under lease to parties of miners, most of whom were extracting rich ore in a tremendous hurry, so as to make a maximum profit before the expiration of their leases. This, of course, interfered with systematic exploitation. The only mill worthy of mention as taken over with the mines was that belonging to the Combination, and even it was of only 60 tons capacity. Therefore, most of the ore was shipped to the smelters at San Francisco (Selby), Salt Lake, and Denver. A little ore was treated by local

custom plants, and most of the ore produced by lessees was sold through local ore-purchasing companies—that is, sampling works—which were unable to receive shipments as soon as the October panic disorganized the money market. On the whole, therefore, the conditions were unfavorable to economy or rapidity of production.

The Goldfield Consolidated is capitalized at \$50,000,000, in 5,000,000 shares at \$10 each. Stock to the par value of \$35,500,000 has been issued. This is quoted at the present time at about \$4 per share, making the market valuation about \$14,200,000. The report shows that the total profit for the year was \$1,760,358, and of this \$782,056 was in the form of royalties paid by the lessees of the Mohawk. When next the shareholder looks for figures of the tonnage from the different mines, for detailed costs, for segregation of accounts, or, in fact, for any such information as is usually given in the annual report of a company operating a large mine, he will find nothing but a confused and inconsistent jumble of figures. For instance, the production of the Mohawk is subdivided into "Ore Shipments (Gross)" and "Royalties—Gross Value." The first must refer to shipments made by the company and the second to those made by the lessees. Then a separate amount is put down to 'ore in transit' without indicating whether it was mined by the company or the lessees. Let it suffice to say that the arrangement of the various statements, as well as special items, is most confusing, even to one keenly interested in unraveling them. A page is devoted to an inventory of surface equipment, from a "Topman's Shelter" to a "Bench for Cutting Wedges", a mere childish enumeration of things without a single figure to indicate the original cost or present valuation. The maps were not made even by an ordinary mine draftsman; they are badly drawn, poorly lettered, and wretchedly printed. The general information regarding the mine is most inconclusive; three pages are given to 'Developments', but the absence of detailed figures as to width and assay-value of ore renders it all meaningless. Mining costs for the Combination are given as \$4.37 per ton and the milling cost for the same mine as \$7.14. Ore already broken is estimated at 24,987 tons, worth \$1,032,075. Mistakes in the additions remind us that in the original prospectus of this company there was an error of \$800,000.

Next comes the question of reserves. This is dismissed in a paragraph of nine lines. It is stated that "there is as much ore standing ready for extraction in the bonanza bodies as has been removed during the past year, i. e., at least \$5,500,000." As to further probable ore reserves it is said that "if the bonanza and low grades are treated together in a mill, I believe there is developed ready for extraction and treatment 1,000,000 tons of an average value of \$25 per ton, which should yield a profit of \$17 per ton." That is, the net profit available is \$17,000,000—a truly magnificent sum. The estimate may be well founded, but no adequate evidence is given nor any data such as would carry assurance to either an anxious or a hopeful shareholder. Finally, there is a parting word concerning "Advances in Geological Theory." The ore-shoots are described as "only extraordi-

inarily rich segregations within greater masses of quartz deposits which range from a few feet to more than 100 feet in width." The work of the past year has confirmed the idea that the lodes are "made up of elongated masses of quartz or silicified material in breccia fissures of great width, surrounding large irregular masses of porphyry." This description is particularly valuable as coming from a mining geologist of high standing, for such is Mr. John W. Finch, the general manager signing the report. Finally, we may add that by digging into this brecciated mass of information we have ascertained that the total output was 31,338 tons, having a gross value of \$6,296,476 or \$200 per ton. As the total profit was \$1,760,358, the net profit per ton was \$56, or 26 per cent of the gross. Having regard to the extraordinary richness of the product, this is a poor result. The company has paid one dividend of 10 cents per share, absorbing \$355,000, and carries forward \$1,517,190. It remains to add that the general manager signing the report resigned two months ago and nothing is published from his successor, who made a careful examination of the mine before he accepted the task of re-organization. Of course, a complete report by the new general manager, Mr. J. H. Mackenzie, would have proved a valuable supplement to that of the late manager, Mr. J. W. Finch, who continues in the service of the company as its consulting geologist. It is assumed that so experienced a man as Mr. Mackenzie would not have accepted the general management unless he had formed a cheerful opinion of the future of the enterprise, and this one inference is worth more to the stockholders than all the confused statements of the annual report of the company that controls the most productive gold mine in the world.

Standards and Definitions.

THE Institution of Mining and Metallurgy, an Anglo-American organization of mining engineers and metallurgists, with headquarters at London, has accomplished a great deal of useful work during the last few years and is entitled to the hearty respect of the profession that makes the whole earth its patrimony. Not being trammelled, as is our American Institute of Mining Engineers, by a clause in its constitution forbidding corporate expression of opinions, the Institution has led the way in standardizing usage and in defining good practice. For example, it has given a highly impressive funeral to the objectionable phrase 'ore in sight,' as being non-descriptive and misleading. By replies received to circulars sent to the members, it was ascertained that this unhappy phrase stood for very different factors in the appraisal of mines; to one man it meant ore blocked out, to another ore presumably existent but not blocked out, and to the public generally it conveyed an idea of certainty wholly foreign to an estimate. The result has been to taboo the phrase and to leave it to the charlatan; moreover, the discussion leading to the definition has done much to clarify notions concerning estimates of ore and to inculcate a carefulness highly favorable to good work among engineers and mine managers.

Next, the Council of the Institution adopted a resolution forbidding members to quote from its transactions in prospectuses "or any other documents published in connection with commercial undertakings" unless the written authority of each writer concerned is previously obtained. This discourages the distortion of descriptive and scientific statements into endorsements of questionable schemes. At the same time the Council recommended all members to insist upon their reports, when appearing in a prospectus, being distinctly dated, published in full, or else summarized only with the approval and signature of the engineer quoted. Of course, this is not binding on the outsider, on the unscrupulous or careless promoter, but the mere existence of such regulations among professional men is bound to influence the financial world and will do much to conserve methods within honorable limits. Only this week we heard of an injustice done to a friend by a reference to his report, without mention of the particular conditions upon which certain results were predicated. Most engineers have undergone the experience of seeing their old reports used in new flotations, that is, a report made on a mine when in a productive stage has been published years afterward when the mine has been depleted of the ore that formed the basis for the favorable opinion of an earlier date. Even well-meaning promoters have summarized the reports of their engineers in such a way as to convey promises not intended by those that wrote them. If the profession does not protect itself the public will not. All such measures are calculated to improve the professional standing of engineers and the Institution is deserving of the cordial support of mining engineers, metallurgists, and geologists the world over.

As if to give force to these suggestions, the Council is to have the right, by a majority of four-fifths of those present, and at least ten members of the Council being present, to expel any member who has committed an offence rendering him unfit to be a member. This is a practical step and will give a punitive power without which the recommendations by themselves might seem academic.

On the top of these activities, a campaign of standardization has been carried forward, with distinct success. 'Mesh' is no longer a haphazard term; it has been disciplined so that a measure of scientific accuracy has been attained. The short ton of 2,000 pounds has been adopted, and the hundredweights and quarters of an archaic terminology have been abandoned in favor of decimals of a ton. A 'miner's inch' is a flow of 1.5 cubic feet per minute and 'stuce head' represents a flow of 60 cubic feet per minute; but even these local terms are to be retired slowly in favor of definite expressions covering the flow of water per minute or per second, in cubic feet or in gallons. Gallon itself is to stand for the measure of 10 pounds of water. Bullion is to be sent to the verbal scrap-heap and returns are to be stated in terms of fine metal. On the whole, this standardization is a notable achievement and we recognize in the labors of the Institution a performance of far-reaching benefit to all those engaged in mining.

Personal.

ALLIENE CASE is at Elko, Nevada.

JAMES W. NEILL was here this week.

H. H. WEBB is here, on his way to Mexico.

W. H. LANDERS is at Wadsworth, Nevada.

PHILIP ARGALL will spend Christmas at Washington.

EDGAR RICKARD made a brief visit to Denver and Salt Lake.

J. POWER HUTCHINS has returned to New York from Oregon.

R. S. BLACK is now manager of the Kalgurli mine, at Kalgoorlie.

M. L. F. Effinger, of Silver Peak, Nevada, is at the St. Francis hotel.

W. E. DEFTY is examining mines in the Tombstone district, Arizona.

F. H. JACKSON lately at El Oro, is now at Inde, in Durango, Mexico.

H. P. GORDON is with the Mohawk mine at Michigan Bluff, California.

D. F. IRVIN, recently at Breckenridge, Colo., is now at Oakland, California.

CLAUDE T. RICE has left San Francisco and is now on his way to New York.

R. J. GRANT has been engaged recently in professional work at Cripple Creek.

CHARLES BUTTERS is expected in San Francisco on his return from New York.

ODELL WILSON, of Salmon City, Idaho, is temporarily at 463 Moss Ave., Oakland.

WILBUR E. SANDERS has opened an office at Los Angeles, in the Union Trust Building.

F. L. MORRIS has returned from Dawson. He has an office in the Monadnock Bdg., San Francisco.

P. C. STOESS will represent Pearse, Kingston & Browne at Seattle. His office is in the Colman Building.

WILLARD S. MORSE, of the American Smelting & Refining Co. is in San Francisco on a tour of inspection.

H. W. DuBois has arrived at Philadelphia, having ended a professional journey to the new goldfields of Nevada.

W. S. NOYES will open an office in the Mills Building on January 1. Since the fire his office has been at Oakland.

J. JEFFREY SCHWEITZER is assistant to the superintendent of the Keystone Mining Co. at Amador City, California.

W. M. DRURY is superintendent of the 600-ton concentrating mill at the Tecolotes mine at Santa Barbara, Mexico.

ARTHUR L. PEARSE sailed on the *Lusitania* from New York on December 14. He will proceed to examine copper mines in Corsica.

FLETCHER MCN. HAMILTON is permanently residing in Torreon, representing the Denver Engineering & Machinery Co., of Salt Lake City.

A. G. KIRBY, mill superintendent and metallurgist of the Goldfield Consolidated Mines Co., of Goldfield, Nevada, was in Denver for a few days on his way to the San Juan district.

JOHN A. RICE has severed his connection with the Chemung Copper Co. at Tyrone, New Mexico, and will resume his practice as consulting mining engineer, with offices at El Paso, Texas.

L. H. TAYLOR, recently in charge of reclamation work in California and geodetic surveys in Nevada, has been appointed supervising engineer with the California-Nevada Power Company.

N. C. GROCH has resigned as general mill superintendent with the New York & Honduras Rosario Mining Co., of San Juanito, Honduras, and has returned to his home at Sandusky, Ohio. He expects to return to Nicaragua, where he has some mining concessions.

General Mining News.

ALASKA.

Preliminary work on the Bonanza copper mines in the Copper River country will be rushed this winter, so that several hundred men may be employed in the spring. The Copper River & Northwestern railroad is being constructed to these mines. A sawmill of large capacity is being shipped to the property and plans have been completed for the construction of a score of buildings.—H. C. Strong, it is reported, has made a big copper find near Mt. Andrew in the Prince of Wales district.—Peter Monohan, William Grogg, and Sidney Woffington reached Valdez on Dec. 3. They brought \$80,000 in gold dust, secured from a bench on Valdez creek, at the head of the Susitna river.—A. H. Brooks, chief of the United States Geological Survey's Alaskan Division, reports that various unfortunate conditions have led to a material reduction in the gold output of Alaska as compared with that of the previous year. Preliminary estimates indicate that the gold production for 1907 will be between \$17,000,000 and \$18,000,000, as against more than \$21,000,000 last year.

ARIZONA.

COCHISE COUNTY.

The Duluth-Chiricahua company has done about 300 ft. of development work this year on its group of claims near Paradise. J. C. Sweeney is superintendent. Some good ore was found in the Eighty-six claim. The cross-cut adit on this claim is about 60 ft. long; in the face of the adit the ore occurs. One of the shafts belonging to this company is 90 ft. deep, the other 70 ft. In the latter sinking had to be suspended until a pump is installed. Consequently a drift was run from this shaft just above water-level; ore has been found in this. On the Sullivan claim belonging to this company there is considerable good copper carbonate ore.—At the Emerald mine at Tombstone the width of the orebody, recently discovered, has not been determined, but the cross-cut which is 30 ft. long is still in ore. The winze is also in ore. This ore is a black copper sulphide carrying some lead and silver. The orebody was found about 50 ft. below the water-level. A new vertical shaft is to be sunk farther up the hill and a little south of the present shaft. The company will soon begin to rebuild the head-frame at the Lucky Cuss shaft. Much assessment work is being done on claims near the Emerald mine owing to the recent developments at that mine.

At the Manhattan mine the force has been increased to ten men; the work being done consists of driving the Demarest and Smith adits and building necessary trails.—Six men are employed on the Jno. A. Dunnean group.—The Calumet & Arizona Mining Co. has started an additional furnace at its smelter in Douglas. It has now the same number of furnaces in operation as before the disturbance in the copper market.—The Anderson-Apache Co. has let a contract to William J. Williams for sinking and timbering the main shaft down to the 300-ft. level; Mr. Williams engaged nine miners from Bisbee.

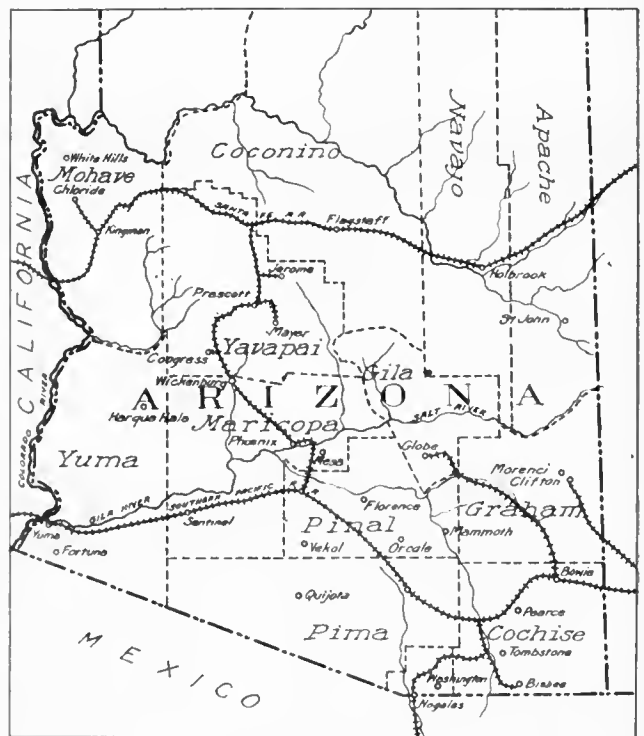

GILA COUNTY.

At the Old Dominion mine progress on the sixteenth level has been rather slow on account of the changing of machinery. A sulphide-bearing vein has been exposed for about 15 ft., but the rich ore expected has not been reached. The ore developed carries about 4% copper. A drift is being extended practically along the foot-wall to ascertain the probable length of the sulphide ore-shoot.—In the cross-cut at the Mallory mine, the sulphide vein has not been reached; a seam carrying a high copper content was found. By Jan. 1 cross-cutting will be commenced at the Gem shaft; the station is now being cut on the twelfth level.—The Miami Copper Co. has been organized to take over the Aisdorf properties in the Globe district. Work on the property began a year ago. About 4000 ft. of development work has been done; three levels have been opened on the Red Spring claim. Until recently 60 men were employed, but owing to a strong flow of water the force was cut down to

half that number. Louis A. Wright, consulting engineer for the company, has called for bids from the machinery houses for a 250-hp. hoist, air-compressor, drills, and pumps; upon the installation of this plant the force of miners will be increased.—The Arichise Copper Co., which recently opened a good vein of copper ore, north of Safford, is making regular shipments.

GRAHAM COUNTY.

While the new furnace at the Shannon smelter is being broken in, the two old furnaces have been put into first-class shape. The intention is to transform these into one large furnace as E. P. Mathewson has done at the Anaconda smelter. When this is done the Shannon smelter will have a capacity of 3,000,000 lb. of copper per month. The company has laid in an ample supply of fuel, so as to avoid the trouble experienced last winter. At the Coronado mine the company has developed a large tonnage of ore. When the price of copper improves, the ore from the New England & Clifton mines, and also that from the mines belonging to the Arizona Commercial Co. will be treated at

Map of Arizona.

the Shannon smelter.—Rich silver ore, carrying some gold, has been found on the 175-ft. level in the Lillian claim. The company is sinking and driving on this ore-shoot.

MOHAVE COUNTY.

At the Treasure Hill mine good silver ore has been found in the north drift.—Good silver ore has also been found on the group of claims belonging to Walter Brown and George Lockwood. The property is between the old Sixty-three and the Treasure Hill mines. The ore was found in the adit, the vein being four feet wide; there is a small streak of rich silver ore in the vein, but the ore is mainly galena.—On the 800-ft. level of the Gold Road mine the west drift has been in good ore for 7 ft.; two shifts are working in this drift. The French shareholders desire to develop the mine to a depth of 1,000 ft. before improving the mill, so as to be sure of the extent of the orebodies. On the other hand, the American shareholders contend that the saving in the cost of milling and the increased extraction will more than pay for the new mill before the orebodies are exhausted.

PIMA COUNTY.

At present 20 men are working at the Twin Buttes property, but the force will soon be greatly increased.—Several new orebodies have been found at the Pueblo mine, near Tucson. The company is preparing to make another shipment of ore.

PINAL COUNTY.

The installation of machinery has been completed at both the Alta and the Oklahoma mines, near Florence, and mining will soon be resumed.—At Ray the Hercules & Arizona Co. has resumed.—In the Saddle Mountain district, at the Two Queens gold-copper property, much development work is being done.—The main adit at the mine belonging to the Central M. & D. Co. is now 450 ft. long; one of the shafts is 182 ft. deep. The force of miners will soon be increased, as considerable development work will be done this winter. The company has made five shipments already.—The Calumet & Arizona company has installed a hoist on its claims near Mammoth.

SANTA CRUZ COUNTY.

At the old Cerro Colorado mine, in Arizona district, 40 men are working. Charles Udall is superintendent. The shaft is 400 ft. deep and will be sunk to a depth of 500 ft., where cross-cutting will begin. Heavier hoisting equipment has been ordered; while the company is waiting for the arrival of that, work has been stopped in the shaft. Development continues in other parts of the mine.

The Nogales Consolidated Copper Co. is continuing development on its property; it has found two 3-ft. veins of free-milling gold ore that assay from \$4 to \$5 per ton.

CALIFORNIA.

ELDORADO COUNTY.

Work is being pushed at the Pre-Volcanic mine, in Pacific district, and the prospects are said to be satisfactory; nine men are employed.—At the Gardner Consolidated mine, in Big Canyon, three men are taking some fine ore from a drift which they are running from the main adit.—At the Mt. Pleasant mine the new company now operating the mine under a bond are preparing for extensive work. The force at the mine will be increased to 12 men on the first of the year.—Wm. Craddock is ground-sluicing on his property in Big Canyon in order to uncover several porphyry lodes.—Forty tons of ore from a mine in the city of Placerville are being crushed in the two-stamp mill of B. Pappina & Son.

INYO COUNTY.

A group of claims in Black Canyon, being developed by Chas. Bishop and J. B. Ellis, has yielded some ore of shipping grade. Copper and gold are present in some of the ore, but the earlier specimens displayed contained much silver and lead. The work done so far has been little more than location requirements, but has shown the existence of strong lodes.—The owners of the Gold Bug and Gold Dollar groups at Snyder's Camp, near old Chrysopolis, recently visited the property and expressed the intention of providing working facilities on a large scale. The principal opening is a shaft 50 ft. deep, from which a drift 50 ft. long has been run on a vein averaging six feet of ore. The ore is said to carry considerable gold. Another shaft 40 ft. deep exposes a vein eight feet wide, carrying gold, silver, and copper.

NEVADA COUNTY.

Now that the Kenosha mine has been unwatered, a crew of men are sinking on a good lode. The new machinery is working well and the shaft is making excellent progress.—It is reported that a good shoot of ore has been encountered in the New York-Grass Valley mine. Only a small crew has been at work, but it is probable that this discovery will lead to the working of the mine on a large scale.—The South Yuba M. Co. has found native copper in its adit No. 6, 400 ft. from the portal. The lode outcrops on the surface 300 ft. wide, and was formerly known as the Red Ledge. A new adit will be started in order to develop the ore at a lower level. A 5-ft. quartz vein was also cut in adit No. 6.—The body of ore recently found in the Idaho-Maryland mine is strong and the walls well-defined. This ore-shoot is entirely separate from that which made the mine famous years ago, when it was known as the Idaho.—At the Norambagua practically nothing is being done, but arrangements have been made for the necessary machinery to resume work in the spring. At the Champion mine, a 6-ft. vein of ore of excellent quality was found on the 800-ft. level;

the find is regarded as the most important yet made on that property. The development was made in the hanging wall south of the Champion shaft, in territory which the Champion company acquired some years ago from the Providence company. The latter company had done much exploration work in that district, and had narrowly missed making the discovery years ago.

L. B. Clark and Henry Goering are opening up a placer mine near Round Mountain.—An important strike has been made in the Young America drift mine on Oregon creek. For several years a company has been tunneling an adit to get beyond the old workings; bodies of gravel thus found heretofore proved of small size, but that recently opened appears of greater promise.

PLACER COUNTY.

(Special Correspondence).—The Three Star mine of Ophir is working about 35 men. It has 10 stamps crushing ore. This is one of the mines that the panic has not hurt. Most of the gold is free.—The Placer Gravel Mining Co. at Last Chance has found the bench at the lower end of their ground; they have been driving for it for some time. There is good gravel at this point.—At the Rubelin quartz mine at Last Chance there has been installed a Pelton wheel, using water under a 90-ft. head to furnish power for the 2-stamp mill; most of the gold here is in free and is caught on the plates. Thirty-two feet of blanket sluices are used to catch the sulphides. The ore yields a little under \$10 per ton on the plates. As far as developed the lead shows up well.—The United Water & Power Co. at Gold Run is using three Woods drills in breaking gravel; this gravel is a hard cement. It is crushed in a 10-stamp mill. Impulse wheels generate power for the mill and air-compressor.

East Auburn, Dec. 18.

SIERRA COUNTY.

Much activity is shown in the mines near Alleghany on account of new strikes.—Glasson and Empfield are developing the Nancy Lee claim on Buckeye hill.—The work of pumping out the shaft at the Independence quartz mine on Wolf creek, below Alleghany, has been commenced.—Cook, Spellenberg, and Devine have found some rich ore at the Bullion mine. This new vein is on the foot-wall side of the one formerly worked.—The Sovereign mine has been closed for the winter, except that two shifts will continue driving the adit.—A small force of men is employed at the Hayes mine.—At the Plumbago mine a rich pocket of gold quartz has been struck. It is in the deepest part of the mine, at a vertical depth of about 1,000 ft. from the surface, and 2,000 ft. from the portal of the lowest adit-level. Three shifts of men operating machine-drills have been mining the quartz, which is sacked and sealed before being taken out of the mine.—The Rainbow mill is crushing 50 tons of quartz per day.

SISKIYOU COUNTY.

The Seiad company has been organized at Palo Alto to operate a hydraulic mine on Seiad creek.—A strike of rich ore is reported from the Taylor Creek basin. While tracing up some surface prospects the owners uncovered a lode which contains specimen ore.—At the Zarina mine, on Taylor creek, power is being developed to operate an air-compressor. A 5-stamp mill is being supplied with ore from the mine.—Welch & Sons have a large force of men installing a hydraulic elevator at their claims on Grouse creek.—At the Fred Beaudry group of placer claims on the South fork of Scott river the ditches and flumes are being repaired; it is intended to work two giants this season.—The mine on Sugar creek, recently purchased by H. S. Hinzey, has about 40 men at work. A sawmill has been installed and buildings for living purposes erected. The men are excavating for a 10-stamp mill.

TUOLUMNE COUNTY.

Troubles have broken out anew in Angels Camp between some of the mine operators and the miners. On Dec. 9 when the night-shift reported at the Lightner mine, they found a notice posted that hereafter miners would have to work nine hours underground. This meant that the men would have to change, and go up and come down on their

own time. The night-shift, numbering about 75 men, refused to go to work. The management of the Lightner removed the notice in the morning and the men returned to work. At the Utica company's properties, where the management was about ready to put on a large force of men the notice is posted. Result, no men are at work. Other mines about Angels are not affected.—The Black Oak mine has been bonded to S. A. Knapp, of Oakland.

IDAHO.

NEZ PERCE COUNTY.

Escallon & Anderson, the San Diego company, and the Wild Rose company are driving adits for the development of their properties in the Pierce City district.—A find of rich ore, it is reported, was made at the Gold Dollar mine; it is owned by Frank Hye and Ed. Ford.—A. Allardyce, of Chicago, has secured control of the Union group, which is situated on Seigle creek; further development work has begun.—Preparations are being made to develop the Occident mine. It is proposed to drive a 1000-ft. adit; this is expected to develop ore at great depth beneath a fine outcrop.—The Bassler M. & M. Co., of Rocky Bar, has begun

Miners' Union, No. 220, was bitterly arraigned. In part the document reads as follows:

"That this organization is a conspiracy in restraint of trade among the States is evident. The mines and mills of Goldfield produce and handle ore that is nearly all shipped to other States and there converted into metals. This organization interrupts and prevents this interstate business. We also charge that this organization is treasonable in character. While perhaps no overt act of levying war or adhering to the enemies of the United States might be proved within the technical definition of treason given in the Constitution, the intent and purposes are ever present. This so-called union carries the red flag in its procession, eschews the Stars and Stripes and lines the walls of its meeting places with anarchistic and treasonable utterances. It has foresworn its allegiance to the United States and placed itself under the blood-red banner of anarchy. So far as the mine owners of the Goldfield mining district are concerned, we have taken our stand and propose to remain there. We will not now nor in the future compromise with crime. All that this Association asks is the privilege of working its properties upon fair, just, and equitable terms. We make no war against labor unions, but on the contrary prefer union labor, believing it to be generally better than non-union labor. On the other hand, if we cannot procure miners except they be members of the Western Federation of Miners, we prefer non-union labor. We do not regard the Western Federation of Miners as a labor organization, but believe it to be an organization controlled by socialists and anarchists, who, parading under the name of a labor organization, desire to produce such turmoil and confusion between employer and employee that their socialistic and anarchistic program may be carried out. We would also call attention to a provision in the constitution of the Western Federation of Miners to the effect that 'no local union or unions of the Western Federation of Miners shall enter into any signed contract or verbal agreement for any specified length of time with their employers.' That is, no agreement for peace is to be made that cannot be broken the next day and the warfare so dear to the heart of the socialists and anarchists renewed. We submit that these declarations themselves are a declaration of war between this organization and trade unions, and place this body beyond the pale of a labor union or lawful organization." Besides asking for the prosecution of the Western Federation, the operators ask for the protection of life and property which comes from the presence of a body of United States troops. The Federal Commissioners commenced work Dec. 16, by holding extended conferences with both General Funston and Governor Sparks. The investigation, it is now believed, will consume fully a month, even though the work proceeds without interruption. Representatives of both sides will be heard, as well as witnesses from the middle party, the citizens and merchants of Goldfield. These different depositions will be recorded by two stenographers and will be used to form the report which will be later submitted to the President.

More men went to work Dec. 16 at the mines and mill of Jumbo town, the site of the richest producing properties in this district, and the place where Camp No. 2 of the regulars is pitched. The Combination mine is now running three full shifts, keeping up work night and day. The Combination mill is admitted to be working short-handed, but its output is almost what it is in peaceable times. The Little Florence Mining Co. has 20 men on the pay-roll, and 50 are expected to be at work tomorrow. The Nevada Goldfield Reduction Co.'s plant is running regularly now with three shifts. The mine operators say that within 10 days, when parties of strike breakers have arrived in large numbers, every heavily producing mine in the district will be working again. Neither military nor civil authorities will be asked to look after these strike breakers. This has been settled. The operators of the different mines have decided to hire and arm their own guards, and they have commenced to make arrangements to feed and shelter them.—The Pittsburg-Silver Peak Co. has secured sufficient power to enable it to operate 20 additional stamps of the mill; it expects to have these dropping by January 1.

Map of California.

driving an adit which will cut the lode at a depth of 650 ft.—At the Potosi mine, the work of sinking the shaft from No. 2 level is in progress.—The Perseverance M. Co. at Flint, it is reported, is taking out some high-grade ore; 11 men are employed.—In a raise from a lower tunnel, the Village Blacksmith M. Co. has found good ore.—The De Lamar company has the poles set and wires strung for its power line from Dewey; electric power will be substituted for steam at the mill.

NEVADA.

ESMERALDA COUNTY.

On December 16, the Mine Owners' Association of Goldfield asked the United States Government to bring suit against the Western Federation of Miners for the dissolution of that organization as a trust, combination, and conspiracy in restraint of trade. The Government was also urged to bring criminal proceedings against the organization, its officers and members, for the same reason. The petition was presented to the Commission appointed by the President to investigate labor conditions at Goldfield, upon its arrival. The petition consists of 6,000 words. The Western Federation of Miners, and particularly the Goldfield local,

LINCOLN COUNTY.

The double-compartment shaft at the California-Pioche mine is now 100 ft. deep and will be continued to a depth of 300 ft.—A diamond-drill has been installed at the claim of the Nevada-Des Moines Corporation, near Pioche. The result of the operation of the drill will be watched with interest by the local mining public, for it is the first attempt made in the district along this line.—Wells, Fargo & Co. shipped through their agent, B. F. Sides, for the Meadow Valley Co., 17 bars of bullion valued at \$17,965.39.

LYON COUNTY.

A contract has been let for driving an adit at the Wilson Gold Mines Co.'s property at Mountain View.—A width of 5 ft. of mineralized porphyry carrying chalcopryite is reported to have been found in the bottom of the shaft of the Yerington Copper Co.'s mine.—The McConnell company is sinking a three-compartment shaft on its property; it is to be continued to a depth of 500 ft.—The 5-stamp mill at the Wheeler mine is treating 10 tons of ore per day; Fred. Flindt is general manager.

NYE COUNTY.

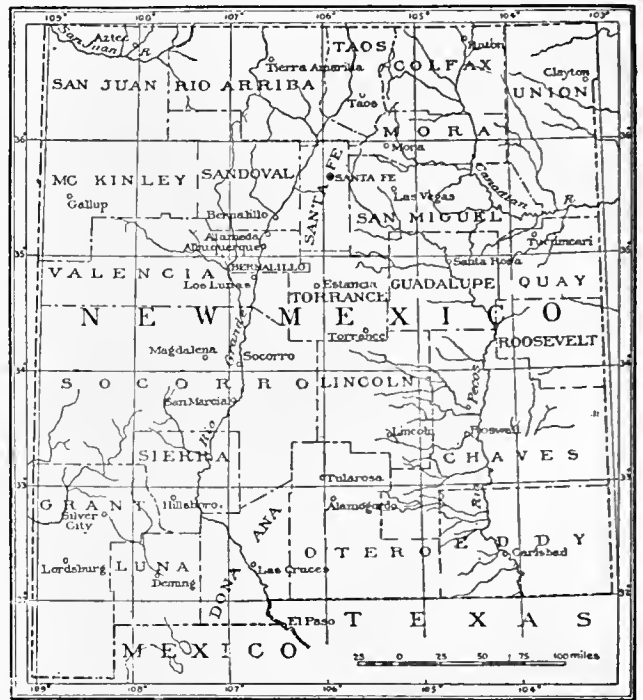

The ore shipments from the Tonopah mines for the week ending Dec. 12, as reported by the Western Ore Purchasing Co., amounted to 1,381 tons. The Tonopah company shipped 1,040 tons; Belmont, 151; Tonopah Extension, 89; Midway, 95 tons. The Tonopah company sent 2,380 tons, the Belmont company 1,080, and the Montana-Tonopah 1,100 to the mills, making the total shipments for the week 5,935 tons, having an estimated value (the shipping ore being valued at \$70 per ton and the milling ore at \$30 per ton) of \$233,030.—The Tonopah Midway is developing the big vein at the 800-ft. level, besides mining and shipping the usual quantity of ore from the upper levels.—The Montana-Tonopah is developing on the fourth and below the fifth level.—The North Star is developing at the 1,250-ft. level, and is sending some ore to the Montana mill from the 900.—The West End is doing such work as seems best to prove its contention in the coming suit with the MacNamara.—On account of the financial condition, it was deemed advisable to stop work at the California for the present.—The north cross-cut of the 850-level at the Little Tonopah is now about 500 ft. long; stringers carrying good silver ore are being encountered frequently. The Little Tonopah ground is being developed by the Tonopah Geodetic company, composed of Los Angeles capitalists; the work has been carried on without interruption for the past two years. The lode porphyry was struck in the shaft at a depth of 810 ft., and after penetrating the porphyry 40 ft., the cross-cut was started to the north. The shaft was continued to a depth of 925 ft.; sinking stopped some time ago.

The Otero mine in East Manhattan is being developed; some good sulphide ore was found in driving easterly 50 ft. from the shaft.—A. D. Sly and J. A. Carr are sinking a shaft on the Saddleback claim of the Round Mountain Extension property. The lode, which was formerly worked in a neighboring incline, is well defined and carries free gold.—Bids are now in for the construction work and lumber on the new Sphinx mill. The winze in the Sphinx mine, which was started last October to connect with the 200-ft. level, has been finished and the orebody is being cross-cut.—The Lemon mill at Manhattan has started on ore from lease No. 13 on the Union No. 9 claim.—The Round Mountain Monster Mining Co. has been steadily at work developing its tungsten property. An adit has been driven into the mountain over 200 ft.; it is expected soon to begin a raise to connect with the upper workings.—A 6-ft. Huntington mill is to be installed at the Madigan lease at Round Mountain.

WHITE PINE COUNTY.

At the Veteran mine the force has been increased to 200 miners; these men are employed principally on the 381-ft. level and in sinking the new four-compartment shaft, which is now 60 ft. deep. This shaft will be sunk to a depth of 450 ft. and will become the main hoisting shaft for the Veteran mine. From the Manhattan adit a winze is being sunk; this is now 80 ft. deep. A raise is being advanced from the lower level to meet this winze; it is thought that connection

will be made by the middle of the month. The ground from the raise, which will be started to meet the main shaft, will be hoisted through the old shaft and this winze; it is thought that the main shaft will be completed by Feb. 1. Work on bins and other construction, necessitated by this shaft, is hastened. The pipe-line to carry water from Holt creek to the Veteran has been completed. This will furnish plenty of good drinking water for the community that will grow up around the Veteran shaft. The new pipe-line is composed of 8 and 6-in. mains, and is 12 miles long. The steam-shovel is now working on the 'high line' between Ely city and the smelter; grading will be completed soon after the middle of the month.—At the Giroux Consolidated mines considerable work has been done since October, but at the Nevada Con. properties very little development work has been done.—At the smelter the main water-line has been completed. The hydro-electric plant, being built to use the overflow from this system, is being rapidly carried along. All the men that can possibly be worked are now

Map of New Mexico.

hastening the first unit of the concentrator at McGill to completion. This will be completed about Jan. 1. Probably the trestle to the mill will not be finished by then.

NEW MEXICO,

The Excelsior M. & D. Co., which operated mines in the Jarilla district, has gone into the hands of a receiver.—The Mineral Point mine, at Hopewell, is being worked by E. C. Sterling.—A carload of new machinery has been received by the San Pedro mine in Santa Fe county; it is thought that when it is installed the smelter will resume operations.—The Laura mine is shipping ore to the Copper Queen Consolidated Co. at Douglas. The vein is 12½ ft. wide in the bottom of the shaft. In driving southward from the shaft a second good ore-shoot was found.—The Twin Peaks M. & M. Co. has ten men sinking the main shaft; they are taking out first-class ore.—The Emma mine is operated under a lease by C. P. Cramer. The weekly shipment varies between two and three carloads of fair-grade copper ore.—It has been decided to erect a 100-ton smelting plant at a point convenient to the property of the Bessemer Copper Mines Co. at Fierro.

SOROCO COUNTY.

(Special Correspondence).—The Treasure Mining Co., owner of the Confidence mine, will rebuild the pipe-line and will re-open the mine, which already shows several million dollars worth of ore. A cyanide plant will be erected to treat the ore from this mine. The process to be installed is the one designed by W. C. Paterson, who has

been doing considerable experimental work on the ore for the past six months. Mr. Paterson is now in Scotland and England, but will return in a couple of months.

Mogollon, Dec. 7.

SOUTH DAKOTA.

CUSTER COUNTY.

Work is in progress on the ground of the Hartwell M. Co. near Lightning creek, about 7 miles southwest of Custer. The main vein is about 40 ft. wide and has been opened in a number of places by shafts, cuts, and adits. It lies between walls of hornblende schist and slate. There are a number of parallel and cross veins on the property, but the principal work has been confined to the main lode; it is estimated that 134,800 tons of ore have been developed.—A large number of men have been employed moving machinery and supplies from Spokane to the Eagle Mountain and King Oscar mines; they are being prepared for extensive mining operations.—At the Reliance mine some important improvements are being made. Machinery recently received consists of one 6-ft. Huntington mill, one 10-drill air-compressor, one 100-hp. electric motor, and five air-drills. When this machinery is installed it is thought the capacity of the plant will be 150 tons per day.—The Providence Mining Co. is shipping 30 tons of amblygonite from its Peerless mine every five days.

LAWRENCE COUNTY.

The Crown group of mines, on Castle creek, was purchased a short time ago by parties represented by Jas. A. Clark. It has just been resampled. A force of men will soon be engaged to start mining and erect the necessary buildings.—At the Connie May Morris group a shaft is being sunk between two strong lodes about 30 ft. apart and when a depth of 100 ft. is reached it is proposed to drive each way to the veins. R. K. Spencer is superintendent.—E. Taylor and N. Lee are investigating the Victor Anna group of mining claims which consists of 440 acres of land.—The new hoist being built for the Minnesota Mines company at Maltland is nearly completed.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Oversight M. & M. Co. is advancing the cross-cut adit on the Pin-Money claim. Although the main vein has not yet been intersected, the adit has passed through other veins which show considerable high and low-grade ore; the ore in the upper half of the face of the adit is of good grade. At present only four men are employed; an addition has been made to the boarding and bunk-house, and the force will be increased about Dec. 15. E. J. Delbridge is manager for the company.—The Copper Key mine has been shut down for 10 days, but is working again; 20 men are employed. The cross-cut from the No. 2 adit has been in ore for the last 78 ft.; this ore is an iron sulphide, carrying gold and copper. A new adit has been started several hundred feet south of the No. 3, to develop the vein about 150 ft. below the No. 2 adit-level; a 100-ton bin is being built near the mouth of this adit. A 32-hp. gasoline engine and a No. 10 Fairbanks air-compressor and receiver are being installed. Two Ingersoll-Rand drills will be used in the future.—The financial stringency has effected some of the companies operating in Belcher district; the Winnipeg company has temporarily suspended operations. The Winnipeg is in a great measure affected by the Belcher Mountain railway being tied up by an accident. This company has made one shipment to the smelters. Further shipments will have to be suspended until the railway is repaired. There is considerable good ore developed in the Winnipeg mine.—The miners employed by the Colville M. & S. Co. on the North Half Colville group have been paid and the mine temporarily closed.—The Blue Bell-Belcher M. Co. has erected a blacksmith shop and substantial winter quarters for the men. Work has been resumed in the adit, which is about 260 ft. long.—A new strike has been reported at the California mine. The shaft and old workings are being unwatered.—The Pearl Consolidated M. Co. has given an option to J. L. Harper, who

represents the Syndicated Deep mines, for the purchase of the Lone Pine, Pearl, and Surprise claims. The purchase price, as agreed, is to be \$10,000, provided this is paid March 1.

Republic, Dec. 12.

CANADA.

BRITISH COLUMBIA.

The output of the Rossland mines for the week ending December 7 was as follows: Centre Star, 4,410 tons; Le Roi, 2,100; Le Roi No. 2, 605; total, 7,115 tons.—At the Hewitt mine an air-compressor and an electric generator will be installed.—A carload of high-grade ore was shipped to the Trail smelter from the Duncan mine near Midway.—The Millie Mac mine, which is situated about 12 miles from Burton City, is expected to produce for shipment between 300 and 500 tons of ore this winter.—It is said unofficially that a cross-cut is being driven from the Le Roi workings for the purpose of cutting the main lode of the Spitzer mine at depth.—The Evening Star mine, which has not been operated since 1902, resumed shipments during the week.—The development of the new ore-shoot in the Le Roi No. 2 mine continues satisfactorily.

At the Trail smelter there was received during the week ending December 6, 5,407 tons, and for the year to the same date 248,029 tons. The ore received last week was from the following mines: Centre Star, 2,940 tons; St. Eugene, 263; North Star, 124; Silver King, 85; Vancouver, 84; Rambler-Cariboo, 23; Whitewater Deep, 44; Slocan Sovereign, 26; Wakefield, 24; American Boy, 23; Ferguson, 28 tons.

At the Le Roi smelter at Northport shipments were received as follows during week ending December 6: Le Roi, 2,517 tons; First Thought, 133; Queen, 24 tons. Total for the week, 2,679 tons, and for the year, 248,029 tons.

The employees of the Granby Consolidated Co. have agreed to accept a reduction in wages. The directors of the company have decided to reopen the mines on December 5, and the smelter two or three days later; they give employment to 900 men when operating at full capacity.—The Venture company has been organized at Barkerville to operate two miles of creek leases on Peters creek, which empties into Lightning creek, seven miles below the town of Van Winkle. Eight men are building a sleigh road from Mather's camp to the lower end of the Venture company's ground.

CARIBOO DISTRICT.

At the China Creek hydraulic mine 90,000 cu. yd. of gravel were piped during the season ending Nov. 2; this, owing to the greater hardness of the bank, is less than last year. The middle ditch has been extended one-half mile, a new penstock built, and the length of the pipe-line increased 400 ft. This has increased the pressure at the monitors from 200 to 300 lb. per cu. in. Two monitors are used, a No. 5 equipped with both six and seven-inch nozzles, and a No. 3 with three and four-inch nozzles. The material is washed into two sets of 36-in. sluice-boxes laid at a grade of 7 in. to 12 ft.; an undercurrent was put in during the season. By using undercurrents the sluice flumes were shortened from 1,000 to 200 ft. The width of the channel is 260 ft., its grade, which has averaged from 7 to 8½%, is less steep near the head of the cut, where it averages about 4 or 5%. During the season 246 ft. of new flume was built on the ditch line to replace worn out flumes and trestles. The new flume is laid on the ground because its cost is no more than if built on trestles and it will be much more durable. The clean-up of gold for the past season showed the yield per cu. yd. to be about the same as last year. B. A. Laselle is managing owner and W. V. Brown, foreman.—At the Nugget Gulch hydraulic mine between 60,000 and 65,000 cu. yd. of gravel were piped during the season, which ended Nov. 3.

EAST KOOTENAY DISTRICT.

The shipments from the mines of the East Kootenay district for the past week were as follows: Sullivan, 600 tons; St. Eugene, 430; North Star, 75; total, 1,105 tons.—The link-belt conveyors for the new sorting-house at the St. Eugene mine have arrived and will be installed as soon as this building is completed. The old platform scales for weighing cars at the mill is being replaced by a larger one.

London.

Ambiguous Statements.—Lack of Information to Shareholders.—Mt. Lyell Co.—Simmer & Jack.—Australian Smelting Corporation.—A Checkered History.—Mining Low-Grade Tin Mine.

I referred last week to the curious case of the Boston Consolidated having to issue new debentures to the tune of a quarter of a million pounds in spite of the announcement made a few months before, that the company would shortly redeem the balance of the then existing debenture debt, and I mentioned that English shareholders were left utterly in the dark as to the change in the financial position of the company which necessitated such an entire reversal of the intentions and policy of the board. Another somewhat similar case has occurred this week. The announcement of the result of the half-year's working at the Mount Lyell in Tasmania is just as ambiguous and incomplete as the statements of the Boston Consolidated directors. The result for the six months ended September 30 is given as follows: "The net profit was £128,728, as against £264,935 for the previous half-year, and the lower profit is due to the fall in the price of copper from £105 to £64 per ton. The average price for copper sold was £96 15s. 6d. per ton." There is obviously a contradiction in this statement. The directors say that the serious drop in profits is due to the drop in copper, yet they also say that the average price obtained was £96 15s. 6d. The English investors are quite non-plussed. The real facts of the case are that, though production did not fall off, yet the sales of copper were curtailed very seriously. The average price obtained was given correctly, but the directors failed to state that only two-thirds of the output was sold. It must be remembered that, though smelting is done at Mount Lyell, the refining is done at Baltimore and the products disposed of in America. As in the case of the Boston Consolidated, the American selling agents either cannot or will not dispose of the copper. Everybody has a different idea of the true inwardness of the present copper slump, and it is not for me to presume to understand the internal workings of the selling agents in America. I simply give this as an example of the way in which English investors in a Tasmanian mine disposing of its products in America get doubly cut off from understanding the course of their business. For myself, I never quite understood why the Mount Lyell does not refine its own product, and so become masters of the output, or even why the company does not ship the bessemer bars to South Wales where there are refineries ready and willing to take such business. No doubt Baltimore quotes a lower price, but the Mount Lyell has already lost, by being under the shadow of the American copper market, a larger amount than it has saved.

Some interesting figures relating to operations and costs are given in the report of the Simmer & Jack Proprietary Mines for the year ended June 30 last. This is one of the largest of the mines on the Rand and is the chief asset of the Gold Fields group. The total ore raised was 881,796 tons, of which 165,117 tons were sorted out and 716,679 tons sent to the mill. The full mill of 320 stamps ran for 352 days and crushed 717,524 tons, being an average duty of 6½ tons per stamp per day. The production of gold in the stamp-mill was 165,810 oz. fine. In the cyanide plant, 535,966 tons of sand yielded 92,569 oz. and 181,558 tons of slime produced 14,110 oz. The treatment of by-products produced 217 oz. The total yield was therefore 273,699 fine ounces, valued at

£1,153,719. The total yield per ton crushed was 7.629 dwt., valued at £1 12s. 2d. The working expenses were £694,506, or at the rate of 19s. 4d. per ton crushed. This was a reduction of 1s. 8d. per ton compared with last year. The amount treated in the previous year was 626,507 tons, yielding 236,444 oz., the duty per stamp per day being 5½ tons. The working profit for the year ended June 30 last was £503,132, which is £129,882 more than in the previous year. The improvement in the results is attributed to the increase in the efficiency of Chinese labor, and the directors are chagrined by the fact that they will now have to discard this labor and look for substitutes. In order to place themselves in a financial position strong enough to hunt up substitutes, only £300,000 is being distributed out of the year's profits and the remainder carried forward. The company has recently installed four tube-mills and contemplates rearranging the slime-plant.

It is probable that before long the smelting plant of the Australian Smelting Corporation at Port Kembla,

New South Wales, will be ready for operation. It has been built for the express purpose of treating lead concentrates obtained at Broken Hill. The history of the company, though short, has been a checkered one. It is really a sort of revival of the old Smelting Company of Australia, which itself had many ups and downs and a queer history altogether. But it is not necessary now to revive these old memories; I shall deal with the more recent events. When Bewick, Moreing & Co. went into the Broken Hill business some two years ago in connection specially with the extraction of zinc from the dumps, they decided also to treat the lead concentrate produced by the Zinc Corporation, and for this purpose negotiated for the plant and other assets of the Smelting Company of Australia, which was then in the hands of a receiver representing the debenture holders, and the Australian Smelting Corporation was formed for this purpose. Nothing but dreary disappointments were in store for the directors of this corporation, and I fancy that if these could have been anticipated, the directors would have decided to start an entirely new works. In the first place, it was found that the debenture holders in the old company were not unanimous in their agreement to accept debentures in the new company in exchange for their holdings. A minority held out against fulfilling the contract and the parties went to law. After spending

some five thousand pounds in this expensive luxury, an agreement was arrived at whereby the minority was bought out for cash. A second and more troublesome difficulty arose when it was found that one cause for the old company's failure was the unsuitability of the site of the works, and it was ultimately decided to move them a few miles to the eastward of Dapto, where a more convenient position on the sea-board could be obtained. Then it was found that the company could not afford to provide port facilities and a deputation waited on the New South Wales Government to urge them to do the work out of the public funds. This point was eventually won and the company became at last in a position to complete the transaction and remove the works. This is now being done, and before many months smelting operations will begin. In the meantime, however, some more working capital will be required. Originally £140,000 capital was subscribed in cash, but no less than £52,890 has been spent in preliminary expenses and getting rid of the recalcitrant debenture holders, while another £30,000 or so has been spent in moving the works and other current expenses. A scheme will shortly be placed before shareholders for the raising of further funds.

The Anchor tin mine in Tasmania is well known as an example of the cheap working of low-grade ores; in fact, it mines the lowest-grade tin ore in the world, the metallic contents recovered being between two and three pounds per ton of rock crushed. Hitherto the income has not quite come up to the expenditure. However, during the year July 1, 1906, to June 30, 1907, the high price of tin enabled the company to make a profit. The average price of the tin sold was £161 per ton, and the cost of production including every possible item, during the year named, was £133 per ton. During the twelve months, 153,738 tons of ore were treated and 225 tons of black tin assaying 71% were recovered. This works out at 3.28 of black tin per ton, as compared with 3.40, 3.59, and 3.97 lb. in immediately preceding years. The average number of stamps running was 87½ and the ore crushed per stamp per 24 hours was 5.85 tons. This stamp-duty was a considerable increase on previous years, comparing with 5.26, 4.98, and 4.74 tons. The total income from tin sold for the year was £30,417, and the total expenditure including smelting at Mt. Bischoff, was £21,525. London office expenses came to £1,062, and debenture interest £1,875, so that there was about £5,000 profit on the year's working. Some interesting alterations have been made during the year in the dressing plant, Wilfleys being put in, displacing the old jigs and vanners.

Butte, Montana.

Effect of Amalgamated Shut-Down.—Re-opening of Boston & Montana Mines.—Pittsburg Failure Affects Butte Mines.—Butte & Bacorn Co.—Cable Consolidated.—Davis-Daly Estates.

During the past week the shut-down of all the mines of the Amalgamated Copper Co., with the exception of those of the Boston & Montana, was made complete, and the suspension promises to be for a long time. The big Washoe smelter, at Anaconda, is gradually being cleaned up for closing, and the North Butte and Butte Coalition companies are left without smelting facilities. The position of the two latter, in their relation to the Amalgamated, is puzzling to the public and to stockholders. It is evident that the directors of the North Butte and Coalition are either in full sympathy with the Amalgamated in its policy, and are willing to suffer loss for their stockholders, or the two companies do not have contracts with the Washoe smelter such as give them any protection

against an indefinite shut-down. Both the North Butte and Coalition mines are shut down. While all the hill mines are closed, those of the Boston & Montana Co. are increasing their output and all the ore is being shipped to Great Falls for treatment. The Boston & Montana mines are being re-opened, and as the men are laid off at the other Amalgamated mines they are given cards to the Boston & Montana and put to work there. The Leonard and West Colusa mines, which had been closed for three months or more on account of fire in those properties, are being re-opened, the fire having been bulkheaded and put under control on all levels but two or three. Prior to the shut-down of the Anaconda hill mines the Boston & Montana confined its mining to the Mountain View, East Colusa, and a portion of the Pennsylvania mine. It is the intention of the company gradually to increase the output of all mines until the capacity of the Great Falls smelter, which is about 4,000 tons per day, is reached. The Mountain View production is being increased from 700 to about 1,400 tons per day, the Pennsylvania from 400 to 1,100, and the East Colusa from 200 to 300, while it is expected to get about 400 tons from each of the Leonard and West Colusa. The mining in the Leonard will be done at the east end, in new stopes on the 1,200, 1,300, 1,000, and probably on the 500 and 600-ft. levels. There will be no mining for some time yet on the 700, 800, and 900-ft. levels. In the West Colusa mining will be done in the West end on the 300, 400, 800, and 900-ft. levels. Only Boston & Montana ore will be mined under the new arrangement. At the other Amalgamated mines a number of men are retained as watchmen, to do repair work, and keep the pumps working. From 30 to 40 men are thus employed at the closed mines. The North Butte and Butte Coalition companies are keeping up development work.

The failure of Whitney & Stephenson, the big brokerage firm of Pittsburg, was chiefly responsible for the suspension of development work by the Butte & Bacorn Co., north of Butte, though some other causes contributed to it. The Pittsburg firm was agent for the company in the collection of subscriptions, and when it failed the collections ceased. It is understood that Whitney & Stephenson had very little money on hand belonging to the company at the time of the failure, and that a large sum of subscriptions remained uncollected. Mr. Whitney was personally much interested in Butte & Bacorn, believing that it would in time develop into a great copper mine, which it has all indications of doing. At the time the company stopped work it was testing a very promising vein northeast from the north cross-cut of the Calumet shaft, although the vein is entirely outside the Calumet ground, being explored through the Zuec and Silver State claims, a little southeast of the Berlin shaft. It is understood that all the money the company will need for development work has been pledged by Pittsburg men, and that much more is available, or will be as soon as there is a relaxation of the money stringency. Pittsburg appears to be hit harder than any other community. Fred. W. Bacorn, president of the Butte & Bacorn Co., has gone to Pittsburg to look into the situation there.

The Cable Consolidated Mining Co., which is operating the Cable mines, some distance above Anaconda, has also been compelled to suspend operations on account of Pittsburg financial troubles, as the company had all its funds in the Fort Pitt National Bank, which has failed. For some time the Cable mines yielded enough copper ore to pay all expenses of mining and development, during its exploration of the gold veins in the property, but when the smelters ceased purchasing copper ore the company had to fall back upon its treasury for development funds. The failure of the Pittsburg bank shut off that supply.

The report from Pittsburg is that the bank will be able to pay up in full and that the Cable funds are safe. The suspension of the Reins Copper Co. was also mainly due to the extreme tightness of money in Pittsburg.

F. Augustus Heinze has retired, or has been retired, from both the Silver Bow National Bank and the State Savings Bank in Butte, both of which he controlled up to the time of his financial troubles. It is announced that he sold his interests voluntarily, as being for the best interests of the stockholders of the banks. The publication of the fact that the treasury of the Davis-Daly Estates Copper Co. had been provided with but \$500,000 upon the organization and flotation of the company instead of \$2,000,000, which the public had been led to believe had been put in the treasury, has added to the further surprise of stockholders. It is promised, however, that the remainder of the fund will be provided by the vendors as soon as money conditions improve, and that development work on the properties in Butte will be resumed.

Toronto, Canada.

The Question of Smelters.—Operations at Cobalt.—Ore Shipments.—Report of Coniagas.—Several Strikes.—Wild-Cat Exposures.

The smelter difficulty continues to be the dominant factor in the Cobalt situation. While the output goes on steadily increasing, and the leading mines establishing their position as producers more firmly, stocks remain at, or fall below, the level to which they were forced by the Wall Street crisis, with no apparent indication of improvement. The sole cause appears to be the difficulty of disposing of the ore on satisfactory terms. Last week's shipments, though from two mines only, established a new record.

The La Rose shipped 497 tons and the Temiskaming 30 tons, the whole of the La Rose consignment going to the smelters at Denver. The New Jersey smelters offer to take ore, and, instead of paying for the silver less expenses of reduction, to return the bullion. This is regarded as unsatisfactory by the mine-owners. The Copper Cliff smelter, owned by the Orford Copper Co., is in the market for ore, and will pay on a graded scale from 94 to 80% of the silver content, according to the grade of ore. To command the highest price the ore must assay 4,000 oz. silver per ton, or over. Payments are to be made in two installments in 45 and 90 days respectively from the date of sampling, and the company reserves the right to pay in silver bullion delivered in New York instead of cash. The payments will be according to the New York price for silver at the date of settlement.

A careful calculation of the number of men now employed in 35 mines in the Cobalt district gives a total of 1,846. Several other mines some distance out are also being worked, and these will easily bring the number up to an aggregate of over 2,000. Shipments continue to increase in volume in spite of the difficulty with the smelters, the total for the week ending Nov. 30 being 956 tons, from the following mines: Foster, 49 tons; Hudson Bay, 67; Kerr Lake (Jacobs), 22; La Rose, 632; Nova Scotia, 46; Silver Queen, 60; Tretheway, 26; Townsite, 21; and Temiskaming, 31 tons.—The Abitibi & Cobalt Mining Co. and the Empress Co. have been merged in a new organization to be known as the Cobalt Majestic Silver Mines, Ltd., in which British capital is largely interested. This company has also acquired a promising native silver location in James township. Abitibi stockholders will receive share for share in the new concern.—A satisfactory showing was presented at the annual meeting of the Coniagas Mines, Ltd., on Nov. 30. The directors' report, covering a period of 11

months ending Oct. 31, showed gross returns of \$779,225, and working and organization expenses \$154,533, making the net returns \$624,762. Dividends and a bonus amounting in all to \$300,000 had been paid, leaving a balance of \$324,762. Ore on the dump was estimated at \$100,000, after deducting cost of concentration and treatment. It was announced that a shaft had recently been sunk to a depth of 60 ft. under the 75-ft. level, the ore at that depth being equal to any yet encountered.—A vein of high-grade ore has been struck in the Foster.—A strike is reported on the 100-ft. level of the McKinley-Darragh mine in Bucke township, consisting of smaltite carrying silver.

As a result of recent exposures of wild-cat operations, a Shareholders' Protective Association is being organized

A Part of Ontario, Canada.

as a medium through which investors in mining and other companies that have raised money by the flotation of stock can investigate their affairs. The association will endeavor to ascertain the facts where companies have failed to comply with the law respecting prospectuses, or resorted to misrepresentations in the sale of shares, and will adopt means for the recovery of moneys so received.—The Toronto and Cobalt branches of the Canadian Mining Institute have nominated Willet G. Miller, Ontario Provincial Geologist, for the presidency, and Alfred E. Barlow for the vice-presidency.

The trial of the charge of conspiracy to defraud against Frank Law and W. Lockhart Russell in connection with the flotation of the Highland Mary Mining Co. has been adjourned from time to time pending the return of Russell from Europe.

Cripple Creek, Colorado.

El Paso Affairs.—The Drainage Adit.—Sound Banking Conditions.—November Production.—Strike in the Rigi.—Another Cyanide Mill.—The Findley Resumes.—Prospecting on Big Bull Mtn.

The interest of the public for the past week or ten days has been centred on the affairs of the El Paso Co. by reason of the peculiar method of letting blocks of ground under the leasing system recently adopted; the 25 blocks, under graded royalties, are to be let to the highest bidders, which is a condition without precedent in the camp. Another feature of interest has been James F. Burns' objections to the leasing system under any conditions, and the driving of the drainage adit by the El Paso Co. for the reason that the contract, as he contends, is without charter rights. Mr. Burns is the largest individual stockholder, but has not been able to sway the action of the directors, who, in spite of his protest, have instituted the leasing system and resolved on pushing the adit to completion if a modification of contract terms is obtained. However, the Drainage Tunnel Co. at a meeting of the board of directors has declared the contract forfeited, as the El Paso Co. has not been able to make the requisite number of feet per month. The Drainage Tunnel Co. will continue the driving of the adit on its own account.

The banks of the Cripple Creek district were the last to use measures of restriction in regard to cash payments and are the first to remove them, resuming payments Dec. 14 as before the situation became unsettled. The business men and public generally, understanding the soundness of the banks under normal conditions, have done everything possible to restore confidence as shown by deposits and absence of withdrawals. The ability to convert the gold of the district into gold coin to meet pay-rolls and other immediate needs is a large factor in this connection, an advantage at the disposal of very few communities.

The gross production of gold for November passed the million dollar mark, the amount being \$1,099,050, an increase of \$121,000 over October. The average value of ore treated by the U. S. R. & R. Co. was \$27 per ton or \$4 higher than for the preceding month. In gross tonnage the smelters reported a loss, but with an increased value, while the Portland mill and several smaller plants gained both in tonnage and value. The total tonnage for November was 47,300 tons and considering that the Golden Cycle mill treated 21,800 tons in October and nothing in November, the improvement is most pronounced, and with the Golden Cycle mill in operation within a few days, December is expected to be the banner month of the year. The railroads having all they can handle with no prospect of a cessation of activity.

The Mabel M. mine, on the east slope of Beacon hill, is reported to have a rich orebody in the Husted workings on the 300-ft. level, being discovered at the junction of two veins in a drift south from the shaft; assays as high as 52 oz. are being obtained. This property is under lease to the Union Leasing Co.—A strike in the Rigi property, just east of the Portland on Battle Mtn., is reported, assays ranging from \$50 to \$145 in gold per ton; a trial shipment has been made, and returns of 2½ oz. per ton are expected.—A cyanide plant for the Blue Bird property is reported to be in contemplation, to cost \$12,000; there are between 50,000 and 100,000 tons of low-grade ore on the dump assaying from \$3 to \$8 per ton; also large bodies of low-grade ore in the upper workings of the mine.

Harrison & Seaver, former lessees on the W. P. H. property, have secured a lease on the entire workings of the Teutonic mine adjoining the W. P. H. Develop-

ment work in the upper workings is all that is planned for the present.—The Findley mine on Bull hill has resumed operations after being closed down for several months; one shift of 160 men is the extent of the activity at present, but it will be increased when the Golden Cycle mill is in full operation. There are several thousand tons of ore ready for shipment from the 1000 and 1100-ft. levels, where there are two large ore-shoots on which development work is being carried forward.—The Carbonate Queen mine on the west slope of Squaw Mtn. is making a bid to become an important producer. After a great deal of development work a 4-ft. vein has been broken into on the 500-ft. level, and several assays show \$500 per ton or better. Should this orebody prove persistent, as it is the largest yet found on Squaw Mtn., that region and Battle Mtn. adjoining will experience a stimulus in prospecting.

With company account and lessees the Anaconda and Mary McKinney estate produced a gross tonnage of between 1300 and 1400 tons of ore for November, with an average value of better than 2 oz. per ton. All the work

A Part of Colorado.

is conducted above the 700-ft. level owing to water below that point. The Pressler and Smith & Altman leases produce the greatest tonnage on lessee account.—The Western Investment Co. reports cutting the extension of the rich ore-shoot from which the British-American Co. has made such profitable shipments.—The Mohican mine, situated between the Ajax and Gold Coin mines on Battle Mtn., has been leased to C. L. Amsden and brother, of Victor, for two years with 25% flat royalty.

The rich orebody opened some time ago in the Old Gold continues to hold out well; the tonnage is not great, about a car a week being sent out; however, the ore runs high, \$50 per ton in bulk is reported, while some free gold-bearing quartz in the centre of the ore is saved separate from the rest of the vein, which is 2 to 3 ft. wide, and seems to be an extension of the C. K. & N. vein, which produced more than \$500,000.—The Golden Cycle Co. owns a great deal of ground on Big Bull Mtn., but no large amount of development work has been done in this part of the district. It is reported that the main shaft will be sunk another 100 ft., or to a depth of 1300 ft., from whence a cross-cut may be run east to explore Big Bull at depth.

Salt Lake, Utah.

Smoke Troubles and Blackmail. — Zinc Ores. — Lower Wages at Bingham. — An Oil Excitement. — License Tax.

There is a strong probability that the Utah Consolidated will close its smelter at Murray and will cease production pending the construction of a new smelter in Tooele county, unless arrangements are made in the meantime to ship the product of the mine to some custom smelter. The farmers of the Salt Lake valley who appeared as plaintiffs in the smoke case, which resulted in the decree of injunction, were approached on the matter of allowing a continuation of operations until March, 1909. They spoke favorably—but their concession had a string attached to it—that of demanding a bonus of \$200,000, in addition to the company being made subject to any damage that might come through the action of fumes upon the farms. In other words, it would cost the Utah Consolidated company practically \$300,000 for the privilege of operating its smelter another 15 months. It is believed here that the proposition will be rejected by the directors and that the fires will be drawn in the near future. The Bingham Consolidated plant is practically down and there is nothing to indicate that the United States can escape the operation of the Court's injunction on January 6. Regarding the lead smelters, there are good reasons to believe that they will continue in operation, as they have made terms with the farmers of the Salt Lake valley.

The miners of Bingham have accepted a lower scale of wages, to take effect on January 1, with good grace. A vote taken at a recent meeting of the miners' union resulted unanimously in favor of the reduction, which amounts to about 25 cents per day. The Bingham scale is called automatic for the reason that should the market price of copper go back to 18c. per lb. again, the present rate will be in vogue.

Much interest is being taken in the Virgin Oil district in southwestern Utah and there is every indication that the field is going to prove to be a meritorious one. Sixteen rigs have been set up and nearly all of them are in operation. Several others are on the way. Southern California capital is largely interested in these ventures.

The directors of the Nevada Hills Mining Co. have posted a dividend of 10 cents per share, or \$100,000, making a total of \$375,000 for the year. The Nevada Hills operates at Fairview, Nevada, but the headquarters of the organization are in this city.

The year has broken all previous records in the disbursement of dividends. A total of \$5,373,992 has been paid out to shareholders of Utah mining companies, not counting what has been received by shareholders of the United States Smelting, Refining & Mining, and the American Smelting & Refining companies, which derive no small part of their earnings from their respective enterprises in this State. But the mines contributing the sum stated are: Beck Tunnel Consolidated, \$340,000; Bingham New Haven, \$22,896; Bullion Beck, \$30,000; Century, \$6,000; Colorado, \$620,000; Columbus Consolidated, \$212,623; Daly Judge, \$225,000; Daly West, \$378,000; Eureka Hill, \$100,000; Gemini, \$100,000; Grand Central, \$147,500; Horn Silver, \$60,000; Lower Mammoth, \$57,000; Mammoth, \$80,000; May Day, \$64,000; Newhouse, \$300,000; Silver King, \$375,000; Swansea, \$5,000; Uncle Sam Consolidated, \$70,000; Utah, \$36,000; Utah Consolidated, \$2,100,000; Victoria, \$30,000; Yankee Consolidated, \$15,000. Last year, the total dividends paid amounted to \$4,163,137, leaving a balance in favor of 1907 of considerably more than \$1,000,000.

Torreon, Mexico.

The Lustre Co.—Torreon Smelter.—The Velardena Smelter and Mines.—A Modern Equipment.—American-Mexico Mining Co.—The Mazapil Copper Company.

The smelting plant of the Lustre Mining Co., at Magistral, in Durango, has two furnaces in operation, and a third furnace is being installed which will be blown in about January 1, 1908. This will give the company the capacity to smelt 500 tons per day. The ore is hoisted and conveyed to the feed-floor of the smelter over a surface tramway. The ores carry from 15 to 20 grams gold and less than 1% copper, being sulphide and oxidized ore in a quartz and lime gangue. Electric power, generated by wood-gas engines, is employed in operating the hoist, blowers, and pumps. R. W. Bissell is general manager, with F. B. Hine as superintendent of the smelter. Magistral is 60 miles south of Rosario, the latter being the terminus of the Parral branch of the Mexican Central railroad.

The Torreon smelter, operated by the Torreon Metallurgical Co., has seven lead furnaces and one copper furnace in operation. The plant handles an average of 1,000 tons of charge per day. The furnaces are all 44 by 144 inches. The charge is fed from mechanical charging cars that pass directly over the furnaces, the feed being distributed by spreaders. Eight reverberatory roasters are employed in treating the lead matte, which contains from 10 to 15% lead. The partially desulphurized matte is then re-smelted. The blast is supplied by five No. 8 and two No. 7 blowers; the intention is to install an additional blower. There are about 4,000 ft. of dust-flues between the blast-furnaces and the main stack. The briquetting plant is of the Henry Moules type. The water supply is derived from wells in the vicinity of the plant. The volume used per day for the jackets and sprinkling is about 1,500,000 gal. Ernesto Madero is general manager of this company, N. Villareal being assistant manager; E. Harms and C. A. Heberlein are superintendent and assistant superintendent, respectively. While this company operates several mines of its own, its plant is largely a custom smelter. Mr. Harms states that there is a great abundance of ore, and there seems to be no falling off of the custom supply.

The American Smelters Securities Co. has taken over the mines and smelter at Velardena, formerly operated by the Velardena M. & S. Co. The smelting plant, which was completed about a year ago, is situated four miles from Pedricena station on the National railroad that extends from Torreon to Durango. The mines are in the vicinity of the old town of Velardena, situated two miles from the smelter site. This company has its own railroad line, running from its smelter to its various mines, aggregating some 20 miles. The Mexican National also operates a branch road between the Pedricena station and Velardena. The mines comprise the Santa Maria group, at Velardena; the San Lorenzo group, in the near-by San Lorenzo range; and the Copper Queen group, 27 kilometres by rail from Velardena. The Santa Maria mines are opened by numerous shafts; they produce between 500 and 600 tons of silver-lead ore per day, a part of which is concentrated at the company's Velardena mill. The mines of the San Lorenzo group comprise the Terneras, La Chona, Los Bancos, and others. These are worked through adits and shafts. The Terneras adit, provided with electric haulage, is about 300 ft. long. The workings extending from this adit are very extensive. These mines likewise produce a silver-lead ore, which is conveyed from the Terneras adit to the bins at Velardena over an aerial tramway.

The Copper Queen, as the name implies, is a copper property in the main, though producing a good deal of silver and lead. There are extensive bodies of oxidized ores here. The mine force at all these mines has lately been much reduced, because, it is stated, the smelting plant has been receiving more ore than it could handle. Wm. Davey is superintendent of the mines. The company has a power-plant at Velardena, equipped with boilers and gas-producers. At present the main electric generators are steam-driven. In the plant, however, are several Crossley gas-engines supplied with fuel from the gas-producers, and they also operate electric generators and compressors.

The smelting plant is considered one of the most modern in Mexico. It is under the general superintendency of Wm. J. Hamilton, who has like supervision over other Mexican plants of this company. There are three

conveyors running to it the material is distributed as required in these great bins. Charge-cars are passed under each bin and loaded automatically. The extensive dust-chambers and flues terminate at the base of a 230-ft. brick stack. The flue-dust and fine are briquetted in the usual manner. The copper matte produced here is shipped to the same company's converters at Aguascalientes, there being no copper converters at the Velardena plant. This smelter is operating at full capacity. The company has excellent outside buildings, affording residences and rooms for employees.

The American-Mexico Mining & Developing Co., under the general management of F. O. Smolt, has three mining properties in the San Lorenzo range, near Velardena. They are known as the Le Roca, Los Libres, and Tecolotes. The Le Roca has a narrow vein in diorite, carrying gold, silver, and copper ore. About 100 tons per

Map of Mexico.

lead furnaces, of a capacity of 150 tons each; and three copper furnaces of 200 to 250 tons each; and the plan is to install one additional furnace soon. There is a roasting plant, consisting of 5 Godfrey roasters and 10 Huntington-Heberlein converters, for desulphurizing the lead sulphides. The crude ore and concentrate are fed to the roasters, and the calcined product is then fed to the converters, which under strong blast reduces the sulphur to about 5%; the product of the converting pots is partly fused together in a matte-like form. The capacity of the roasting plant is about 125 tons per day. This material is conveyed to the charging floor and mixed with the oxidized ores and briquettes that go to the furnaces. Each blast-furnace has an elliptical double-brick-lined settler, 4 by 12 ft., inside measurement. The slag is handled in 10-ton slag-cars, pulled by electric locomotives. The charge is fed into the furnaces automatically from charging cars hauled to the feed-floor by electric locomotives. The sampling plant, and the system of conveying the ore from the sampler to the 12 charge-bins, of 3,000 tons capacity each, is of the most modern and complete type. Over the bins referred to is an electrically operated portable steel bridge, and by means of

month were mined in 1905. The Los Libres produces gold, silver, and lead ores, quite silicious, occurring as deposits in limestone. A considerable tonnage has been produced. The Tecolotes is 6 miles north of Velardena, and produces an arsenical ore, carrying lead, gold, and silver. This company has a two-furnace smelting plant near Velardena—one copper and one lead furnace. It was erected in 1904-5. It was operated during the latter half of 1905, and a part of 1906, but it is idle at present. M. W. Sheafe, of Watertown, South Dakota, is president of the company.

The Mazapil Copper Co., which is operating both copper and lead mines at Concepcion del Oro, State of Zacatecas, has a copper smelting plant of three furnaces at Concepcion, and a lead smelter of two furnaces at Saltillo, both of which are active. The company employs 7,000 men, and its annual production is approximately as follows: Metallic copper in matte, 3,700 tons; lead, 7,000 tons; silver, 1,200,000 oz.; gold, 10,000 oz. This company owns the narrow-gauge railroad extending from Saltillo to Concepcion, distance about 80 miles. P. E. O. Carr has just taken the general management of the company, with offices at Saltillo.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A BELT CONVEYOR does not operate satisfactorily on an angle much greater than 20° ; this is due to the fact that the ore will not stick to the belt. When the grade is steep the rollers supporting the belt must be placed close together to prevent bumping of the ore as the belt passes over the rollers.

If the company fails to perform the necessary annual work to protect its unpatented mining property from re-location, a stockholder may perform it and recover therefor from the company. Work done by such stockholder for that purpose is legal and valid and will preserve the property from re-location.

RESUEING consists in blasting the waste and cleaning that away before the ore is blasted. When machine-drilling is used, the holes in the waste and the ore are drilled from the same set-up; when hand-drilling is used, the waste is drilled and blasted before the ore is drilled. Resue is sometimes improperly called desue.

AT the end of a shift it is customary to hang the cages even with the collar of the shaft; this is to prevent objects or persons from falling down a shaft. It is a poor policy for it greatly hinders the natural ventilation of the mine. A guard rail is generally sufficient, but a gate can easily be made to be used for guarding the shaft when hoisting has stopped.

VENTILATION CONDITIONS in metal mines can be judged fairly well by the amount of carbon dioxide in the air; generally there is a relation between the percentage of carbon dioxide and that of the other more injurious components of mine air. In Western Australia the law limits the percentage of carbon dioxide, permissible in mine air, to 1.5 parts per 1,000.

ON THE RAND generally one white man and five Kaffirs run two air-drills; in some cases one white man and seven Kaffirs run three drills. Eight 6-ft. holes is considered a shift's work for two machines; these holes break on an average two fathoms of ground. The cost is as follows: One white man, £1 5s.; five Kaffirs, 15s.; powder for two machines, 16s.; maintenance, 4s.; total, £3, or \$14.55 per fathom.

THE object of pooling stock is usually defined in the agreement. Sometimes it is to create or consolidate the voting power of the stock, thus perpetuating control of a given faction, and is then called a 'voting trust.' More frequently its object is to prevent vendors' or promoters' stock from coming into competition on the market with treasury stock, or promoters' stock competing with vendors'. It is difficult to infer the object without full knowledge of all the circumstances.

DIRECTORS have no power to deal with the stock of the company's stockholders. The company has no interest in its issued stock and cannot bind the stockholders through the action of its directors. A pool of the stock formed, or continued, by order of directors, is of no legal force, and the stockholder is entitled to the delivery of his stock out of the pool. In fact, there are but few pooling agreements, even if made by stockholders, which may not be repudiated or broken by any of the parties to it. Many of them are illegal and contrary to public policy.

THE important saving that can be accomplished by close sorting of ore containing much waste is shown by the following costs, taken from the reports of the Jumpers Gold M. Co. (Transvaal): For year ending July, 1906, sorting 17 to 18%; recovery per ton, 32s. 11d.; working costs per ton, 23s. 9d.; profit per ton, 8s. 2d. For quarter ending October, 1906, sorting, 22%; recovery, 39s. 6d.; working costs, 27s.; profit, 12s. 6d. For November, 1906, sorting, 22%; recovery, 40s. 6d.; working costs, 27s. 6d.; profits, 12s. 6d. For December, 1906, sorting, 38%; recovery, 44s. 7d.; working costs, 30s. 9d.; profit, 13s. 10d. Of the 38% sorted, 20% was sorted in the stopes and 18% at surface.

THE president, or secretary, or the general manager of a company, are officers to whom a stockholder has a right to apply for information as to the condition of corporate affairs. While the extent of privileges to which stockholders are entitled depends somewhat upon the law of the State under which the company is organized, or where its business is carried on, it is a general rule that where the officers of the company refuse to comply with a reasonable request of a stockholder for information, such stockholder has a right to demand an inspection of the books of the company, and this right may be enforced by the courts. Frequently the law provides a penalty for the refusal of such reasonable requests.

THE INCrustING ACTION of hydrous calcium sulphate in the cyanide solutions passed through filter-presses has caused considerable trouble where sulphide ores are roasted before being treated with cyanide. The removal of this incrustation from the plates of the filter-press is quite expensive. Pneumatic tools and 'sand-blasts' have been used in cleaning these; the latter is the cheaper and the more effective of the two when the plates are badly incrustated. This costs about \$4.80 per plate besides the cost of removing and replacing the plates. At the Great Boulder Main Reef mill, A. Wauchope has constructed a furnace in which these filter-plates are baked at a low temperature for 24 hours. This de-hydrates the gypsum, and then it can be easily removed with brushes made from stout steel rope. The total cost of removing, cleaning, and replacing the filter-plates was by this method about \$2.50 per plate.

TO GEORGE F. BECKER we owe the following formula regarding interstitial space in sediments. When a space is filled with spheres of equal diameters but of such size that each sphere will be in contact with 12 others, then, no matter what the diameter of the spheres may be within these limits, the interstitial space bears the following constant ratio to the whole space:

$$1 - \frac{\pi}{3\sqrt{2}} : 1, \text{ or } 25.95\%.$$

In the case of sandstone most of the open space between the component grains is unfilled and this formula was found by George F. Becker, and still later by C. R. Van Hise, to be approximately correct. In the case of conglomerates much of the interstitial space between pebbles is filled with sand and silt so that the above formula is not applicable. Assuming that the conglomerate were composed of spheres fulfilling the above requirements, and that the interstitial spaces between these larger pebbles were filled with smaller spherical pebbles, whose size also agrees with the requirements of the above formula, then the ratio of the interstitial space to the whole volume would be as

$$\left(1 - \frac{\pi}{3\sqrt{2}}\right)^2 : 1;$$

in other words, the interstitial space would be only 6.73% of the whole space.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Capitalization of Rand Mines.

The Editor:

Sir—In your issue of November 2, Thos. H. Leggett says that the Rand mining companies are not over-capitalized, and uses as an argument the fact that certain companies return high rates of interest on the nominal capital. The nominal capital means very little, as most of the mines on the Rand have raised their cash capital at high premiums, and it is on this capital that interest must be paid. The Witwatersrand Deep, for example, raised part of its working capital at 50s. per share and part at 80s., and the dividend of 40% on the nominal capital means only 10% to those who paid 80s. for their shares. So with the Robinson Central Deep; working capital shares have been issued at 85; the dividend of 75s. on the nominal is really only 17½% on the paid-up capital. I do not know what the Rand Mines sold their working capital shares for, but I know that the 5s. shares were as high as £13 in the market in 1902 and are now about £5. The dividend of 120% or 6s. per share, not 180%, is only 6% on the present price. These are, I think, favorable examples of Rand mining companies. Mr. Reyersbach, in giving evidence before the Commission on the Mining Industry, now sitting at Johannesburg, showed that, in 1906, 39 companies paid dividends averaging only 3%, after allowing for amortization of capital, on the market valuation of the shares. It is largely due to the fact that the Rand mining companies yield such low returns as a whole that fresh capital for new ventures is hard to raise.

W. FISCHER WILKINSON.

London, November 27.

Thawing Dynamite.

The Editor:

Sir—In regard to the thawing of dynamite, the clipping herewith, taken from a prominent Spokane daily, may possibly convey to your readers some facts which are new to them:

"Joseph Plastino, one of the contractors, accompanied the injured men to Spokane. In telling of the accident he said: 'When the dynamite is frozen the men always put it over a fire and thaw it out. When it catches fire, it blazes up like a roman candle. The men had gone back to their work, when they saw the dynamite blazing and ran over to the fire to put it out. They can usually do so by pulling it away from the fire and smothering the blazing portion of it. The foreman of the gang saw that the men could not get there in time to save the dynamite and started toward them to tell them to get away from it. He yelled at them, and just then the explosion occurred. One man was blown all to pieces and the four others were all badly mutilated.'"

Comment is entirely superfluous.

FRANCIS A. THOMSON.

Pullman, Wash., November 21.

[Small quantities of dynamite can be safely thawed by placing it in a small box constructed to set in a box about 16 in. larger than the smaller one. In the open space between the two, green manure is rammed. The top of the box should have a small opening in it leading to the open air. Owing to leakage of dynamite, which may occur, the manure should be changed occasionally. An-

other simple way is to have the dynamite placed on racks near the top of a large box. A can filled with hot water is then placed in the box to supply the heat.

Rules for the Guidance of Employees Underground.

The Editor:

Sir—I venture to suggest the following additions to the rules published in your issue of October 19:

1. No employee, other than the man especially hired therefor, shall carry powder underground in the skip or cage without especial permission.

2. Machine-men and miners shall give a list of the number of drills and tools used by them on each shift to some authorized person, or shall mark same on space provided therefor.

3. Machine-men and miners, before relieving their partners of the preceding shift, shall inquire of the shift-boss for any missed holes, or shall look for list of same on the board provided therefor.

4. Where a station-tender is not employed, there shall be an added number of bells to the regular station-signal to be used by the cage-tender in signaling to raise or lower the cage to any station.

AUGUSTINE LAWRENCE.

El Oro, Mexico, November 10.

A Word for the Miner.

The Editor:

Sir—During the past few months the papers and magazines have been full of references to the trial at Boise, the former troubles in the Cœur d'Alene and in Colorado, and the Western Federation of Miners, and nearly every editor and journalist has taken the opportunity to comment upon the miner and his ways. People who have read these things, and who are not familiar with conditions in mining camps, would be led to believe that the average miner is a most undesirable sort of man, drawing high wages, working short hours, and leading a free irresponsible sort of a life. While no one can excuse the lawless outbreaks that have occurred, it is only fair to the miner to state that his path is not strewn with roses, and often the mining companies are not entirely blameless. You hear of an outbreak, or act of open violence committed by the miners, but you do not hear of the thousand discomforts, annoyances, and exactions that have gone before; nor is it understood that it is the presence of a few agitators from outside, or at worst, simply a mob spirit, with which any body of active rugged men can be imbued if some few clever men deliberately set about it, that precipitates trouble of this kind.

Leaving aside, however, the whole question of the Federation and its policy, and the inevitable war over the division of profits that must always be waged between capital and labor in the mining camps or wherever a large number of rough free-thinking men, without home or family ties to steady them, and living in a most unsocial way, are employed by a corporation whose principal idea is dividends, and whose policy may be dictated by some far-away office; it is a pity that the conditions under which the average miner lives and works are not better understood. If some of the writers who have been contributing so freely to the papers during the past six months could live with the miner for a couple of years, they might have different ideas, and would certainly feel a little more charity for this class of labor.

But in respect to publicity, as in many others, the miner is either poorly represented, or entirely misrepresented. Of course, there is a physical reason for this, since outside of the fact that the average miner possesses

but little literary education, no man is able to do a hard day's work at manual labor, and then exercise his mental self very much. And the more he develops the physical side and thus becomes more familiar with the miner's side of the question, the less he is apt to write intelligently about it. However, there is an increasing tendency for men with a technical education to go underground, so probably we may expect to hear that side of the question more coherently discussed in the future. Today there are men working in nearly every camp, who could contribute useful accounts of the miners' side of the question, and as the columns of the technical journals are open to them, it seems as though this sort of write-up should be more frequently seen.

The average employee of a mining company can either accept the treatment offered him, or get out. He has no appeal, no chance to be heard; if he takes exception to some arbitrary rule of the management, he gets his time. If he moves to a new camp he meets the same conditions.

Take for example the Cœur d'Alene region in northern Idaho; this is considered a good place to work, but there are a lot of things that are far from ideal. In the first place, to get work there, it is necessary to go through an employment office, maintained by several of the larger companies. Instead of going to the mine foreman for a job, the man must go to Wallace and get a 'letter' before he can go to work. Twice a day he takes his place in a long line and waits his turn to see the head of the employment bureau. When he finally gets into the sanctum sanctorum, the superior being who dominates it gives him a negative grunt or a shake of the head. If he looks pretty husky, he may be told to come back on the morrow. Then he has a day of enforced inactivity on his hands. This may continue for a week, a month, or longer. When he finally does get a chance, he does not go to the mines he wants to work in. If he asks to go to the Tiger, he will probably be sent to the Morning. If he wants to run a machine in the Last Chance, he will be put to tramming in the Standard. Whatever he wants, it seems to be considered good discipline not to give it to him. If he kicks at all, he may as well leave the camp at once, for Jack Bayne never forgets, and his chances at the employment office will thenceforth be slim. Once on the job, his troubles are not over. If unmarried, he must live at the company boarding house, \$1 per day being withheld from his pay for meals, and room charged extra. If married, he will find it best to trade exclusively at the company store. Also he is expected to vote as his boss suggests, stay away from dances given in the Miners' Union hall, and become as nearly as possible, a subservient impersonal being. Regular hospital fees are subtracted from his pay. Monthly payments for insurance are deducted from the amount due him, although if he be single there is no insurance whatever about it and not one cent is paid to anyone if he is killed.

It is a pity that some of the writers who criticise the miners could not go, for instance, to the Standard boarding-house at Mace, and eat the sloppy meals, change in the crowded filthy dry-room, and sleep in the little dirty rooms with two railroad lines running directly under the windows. Working on the night-shift, sleep during the day is impossible. If you retire at 3 A. M. you will be awakened at 5:30 by a husky janitor pounding on your door with a section of rubber hose. All day there is noise, and in the summer, heat and flies. Underground the cry is more work, more muck. It is a strenuous existence, with few diversions. Everybody has heard of Al. Page's boarding-house at Wardner, for the employees of the Last Chance. He is understood to have a life contract with the Federal company, entitling him to the patronage of all the men. During the winter, pneumonia

plays havoc with the men at the Morning, a wet mine. The whole country is dominated by the Federal company. The Tiger Mercantile company, where you are expected to buy your supplies, is owned by Federal officials. The Cœur d'Alene foundry at Wallace is owned by mine managers and superintendents. Every time they O.K. a foundry order they vote money into their own pockets. All mining men in Idaho know of the struggle the owners of the Hercules mine had to keep out of the clutches of the Federal company.

This is the country in which the Bunker Hill & Sullivan mill was blown up. That was the only bad break that has been charged against the men for ten years, it being precipitated by a cut in the already low wage scale at the Bunker Hill mine. If the cumulative injuries that the men have stood at the hands of the companies were balanced against this one, the result might not look bad for the miners. The men working underground here are a good lot. They have had a bad example set them for years by the companies themselves, and they have been stirred up occasionally by professional trouble makers, but on the whole they have taken their medicine quietly, and behaved as well as might be expected.

These things could all be written up in detail. There is no reason why they should not be, and the same is true of every camp. The conditions under which the men work in the Cœur d'Alene are not especially bad. In fact, as I have said before, it is considered a good place to work. Anyhow, there are two sides to all questions, and the miner's side hasn't been given enough prominence in the matter that has recently been written about them.

B. N. W.

Spokane, December 1.

[We are glad to have the case of the working miners stated by one in touch with them.—Editor.]

Diamond Drilling.

The Editor:

Sir—In your issue of Oct. 12, Mr. Lewis T. Wright states in his article on diamond drilling that the average cost of wear on carbons per foot is \$2.25. The writer has had considerable experience in contract drill-work in Colorado, doing in all some 15,000 ft. at a price of \$2 to \$2.50 per ft., furnishing everything but power. Carbons were at this time from \$43 to \$75 per carat, almost the same as at present. The work covered all kinds of rock, from very hard to soft; a great deal of hard fine-grained quartz porphyry and flint being drilled, yet never did the cost of wear on carbons exceed 75c. per ft. About 80% of the holes drilled had to be cased, causing extra reaming, but the average wear on carbons used did not exceed 50c. per ft. Broken up and caving ground is always more expensive than straight hard ground, owing to loss of time (the stones being chipped in the holes) and the reaming necessary to case off the cores. Frequently the high wearing cost on carbons is due to the inferior grade of stones used. The selection of stones is a difficult matter and can only be done properly by one who has had large experience in selecting. The average lots of stones got from the carbon brokers will not give 20% of serviceable carbons, yet all may be, to look at, splendid stones. Hammer testing is the only way to try stones properly, and few men can test them in this way. Under ordinary normal conditions, and with good setters and runners, using first-class stones, the cost of drilling should not exceed \$2.50 per ft. for holes up to 1,000 ft. in depth.

El Cajon, Cal., December 2.

Tube-Mill Lining.

The Editor:

Sir—In your issue of November 23 H. W. Hardinge claims credit for the so-called El Oro liners.

In fairness to him and to all concerned, I can state that the El Oro liner was in use at the El Oro mill at least 18 months before his patent was granted. Lately I have seen mention of the El Oro liners, giving credit for the invention to the Dos Estrellas mill. As I was responsible for their introduction at the Dos Estrellas, I take pleasure in correcting this error.

The rib-liner mentioned was invented by J. R. Brown while in the employ of the El Oro Mining & Railway Co.,

Interior of Tube-Mill.

and was later slightly modified by E. Burt, the present cyanide superintendent of the same company. Said liner has been in use at the El Oro mills for over two years, to my certain knowledge; and about 18 or 20 months since, I had same copied and put into the tube-mill at the Dos Estrellas plant. Other parties in El Oro secured the Mexican patent rights for Mr. Brown's liner, and I believe that still another patent for a ribbed liner has been granted by the Mexican Government.

I enclose a photo of the interior of the tube-mill showing the El Oro liner, taken in January or February of the present year. The fairy story going around that the invention was purely accidental, is, I believe, wholly unfounded. The ribbed liners were made with the idea in view of being able to use the pebbles as liners without the use of cement, and not to give the pebble a longer drop.

C. E. RHODES.

Guanajuato, November 29.

The Editor:

Sir—Referring to your issue of November 23, and to an article by H. W. Hardinge, we beg to say that a reference to the U. S. Patent Office files will show that on June 13, 1906, Joseph Rodney Brown, of Los Angeles, (formerly of El Oro, Mexico), applied for a patent on "lining for grinding mills." The patent was allowed and issued on August 27, 1907, and bears number 864,357.

Three claims were allowed, namely:

1. A lining plate for a tube-mill and recesses therein for holding grinding bodies, said recesses being somewhat wider at the portion adjacent to the axis of said mill than at the portion remote from the axis, and adapted to retain material wedged therein.

2. A lining for a tube-mill comprising a series of ribs formed upon the interior surface of said mill, said ribs being narrower at the portion adjacent to the axis of said mill than at the portion remote from said axis, and grind-

ing bodies held frictionally in the recesses between said ribs.

3. A mill of the character described comprising a drum adapted to contain material to be pulverized and a grinding or abrading material, said drum being provided with a lining having recesses adapted to retain the grinding material wedged therein.

As Mr. Brown's U. S. application was dated June 13, 1906, and Mr. Hardinge's Mexican patent was issued January 22, 1907, and further, as it requires two to three months time in which to secure a Mexican patent, it would seem that Mr. Brown was the prior inventor of the El Oro tube-mill lining.

BLAISDELL COMPANY.

Los Angeles, December 6.

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

Sir—Yours of October 2 is to hand. The question you put is difficult to reply to. To begin with, the form of the question is indefinite; the expression "coarse gold" is a relative one, and gold that would be coarse from a cyanide man's point of view might be classed as fine gold by the alluvial miner. Of course your inquiry refers to ore and not alluvion, but it is quite conceivable that there may be ore carrying gold which even the alluvial miner would call coarse. The real point, however, would seem to be, not the condition of the gold as it is in the ore, but as it is in the pulp after having been comminuted for purposes of extraction; this again would necessitate the assumption of some stated degree of comminution. Before trying to reply to your question I should prefer, with your permission, to re-state it more definitely, if I can, while still preserving what I take to be the fundamental point at issue. If in so doing I have failed to grasp the exact point at which you were aiming I hope you will put me straight.

"Given an ore which, after having been ground or crushed or otherwise reduced to a pulp sufficiently fine to pass a 26-mesh screen, still contains, as well as gold finely divided, particles of gold that are too coarse to be dissolved by cyanide solution within a reasonable time and by the methods in commercial use at the present day, what steps would you take to save the coarse gold, which otherwise will escape solution in cyanide?"

The principal difficulty I find in replying to this question lies in the danger, which I have often had occasion to note, of trying to generalize in regard to the metallurgical treatment of gold and silver ores. It seems to me that before one could make a pronouncement as to how best to deal with "coarse gold" it would be necessary to study the particular conditions of an individual case, and even then the conclusions arrived at would not necessarily be applicable to any other mine or ore whatever.

I suppose that the competing methods in such a case would be, on the one hand, plate amalgamation, with or without subsequent cyanidation of the tailing, and on the other, re-grinding or otherwise finely subdividing the whole of the ore, or that part of it that accompanies the coarse gold, and cyaniding the whole without previous amalgamation. If you are disposed to doubt whether the latter is a legitimate and effective alternative to the former, I may state that I have personally had experience of instances where it has shown itself so to be. It is possible that there may be cases where the gold is too soft and pure to be readily disintegrated, but, if so, it would no doubt become flattened out into thin plates, which would be acted on by cyanide as rapidly as if it were mechanically subdivided.

To return to the first of my alternatives; I think that its adoption would rather depend on whether the gold, both coarse and fine, is easily detachable from the quartz, or in other words, it would depend on whether any considerable quantity of the gold was mechanically locked up in the quartz grains and therefore needed especially fine grinding to render it accessible. If, after plate-amalgamation and cyanidation of the tailing, the coarse sand did not contain sufficient insoluble gold to pay for fine grinding, then I should be inclined to declare in favor of my first alternative. If, on the other hand, the coarse sand showed sufficient residual inaccessible gold to indicate a profit on fine grinding, I should be content to recover all my gold by cyanidation alone.

It may be asked, why should these alternatives be considered mutually exclusive? Why should one not get all the gold possible by preliminary amalgamation, whether it be fine or coarse gold, and then re-grind, if necessary, prior to cyanidation of the tailing? The principal reason seems to me to lie in the difficulty of plate-amalgamation when crushing in cyanide solution. I am aware that some metallurgists have combined these two principles, but I think that the practice has not been widely adopted, and my own experience of it has not been encouraging. Moreover, if fine grinding be indicated at all, it is as easy to re-grind at one stage of the proceedings as at another, and if such re-grinding permits the cyanidation of all the gold that could otherwise be caught on the plates, why go to the extra trouble and expense of using plates?

Again, it may be asked, why crush in cyanide solution? Well, that is rather a vexed question, but I may state the fact, for whatever it is worth, that Mr. Charles Butters, after a plentiful experience of water-crushing, has deliberately adopted the practice of milling in cyanide solution in all the plants controlled by him, whether crushing ore from a mine or treating old tailing, and that this has been his invariable custom for at least seven years past. If I were asked what I considered to be the special advantages of this method I should say: First, the increased rapidity in the solution of the precious metals, which materially shortens the subsequent treatment and therefore reduces the size of the cyanide plant necessary for a given tonnage. This is especially marked in the slime portion of the pulp, where it is no uncommon thing to see from 70 to 80% of the gold contents passing into solution before treatment in the slime-vats begins.

The second great advantage I should ascribe to the method would be the fact that the introduction of large quantities of water into the solution stock is thus avoided. It is obvious that, considering any cyanide plant as a whole, no more water can be taken into the system daily than is withdrawn from that system in the same period; consequently, if, with every ton of slime, we take into our plant a ton of water, then for every ton of slime residue discharged we must get rid of a ton of solution in some way or other. Some do this in the form of moisture in the slime residue; and others, who prefer to displace part of this moisture (which, be it remembered, is solution) by water, run to waste an equivalent quantity of solution from the tail of their precipitation-boxes, so as to preserve the balance in the system. This difficulty is much accentuated where the slime residue is treated in filter-presses or vacuum-filters; it is to some extent mitigated where double filtering is practised, that is, where the excess water is extracted from the slime before cyanide solution is added, though even here, when the cake contains 25% of moisture, for every three tons of slime a ton of water is introduced into the system and a corresponding ton of solution has to be eliminated at some point,

rendering it difficult or impossible to give a displacing water-wash to the residue cake without running to waste weak solution. It is bad enough to have to throw away solution carrying cyanide even when its gold contents are nil or 'traces,' but I fear that in too many instances that so-called 'waste' solution is the vehicle of serious gold-losses in addition to the loss of the contained cyanide.

In the foregoing remarks anent the use of cyanide solution in the mill I have allowed myself to wander rather outside the limits of the matter under discussion, but I must ask you to excuse this on the ground that it seemed necessary to explain the position I took up in regard to the point at issue. To return to the subject of your question, I am inclined to think that there is a tendency to exaggerate the difficulties in cyaniding caused by coarse gold. At the mine where I am at present engaged the ore contains a considerable quantity of visible nuggetty gold, but we do not seem to have any trouble on that account. We clean-up some coarse gold periodically from our Huntington mills that has failed to pass an average mesh of about 25 holes per linear inch (several different sized screens are in use on different mills, and the coarsest of the sand issuing therefrom is re-ground in pans), but that is the only place where coarse gold makes its presence evident. The following is a representative screen-analysis of the sand portion of the pulp going to the cyanide plant:

Mesh.	%
+ 40.....	1.0
- 40 + 60.....	32.1
- 60 + 80.....	16.3
- 80 + 100.....	11.3
- 100 + 150.....	21.7
- 150 + 200.....	8.9
- 200.....	5.7
Slime.....	2.9

Concentration of this pulp has now been discontinued, but formerly it used to be passed over Frue vanners before going to the sand-plant. In the course of one of my experiments I took a sample of the resulting concentrate, which assayed \$348 per ton in gold (besides the silver, which we are not now concerned with). If there were any coarse gold liable to give trouble in the sand-vats it would surely be well represented in this concentrate, and yet three days' agitation in a bottle with cyanide solution sufficed to dissolve 95% of it without further grinding or sub-division of any kind. (The same concentrate when treated with the sand in the ordinary course without separation, yields about 97.5% of its gold contents.) Now, even if the remaining 5% in the above experiment be considered to be all "coarse gold" in the sense of our definition, and if in our actual treatment we did not succeed in dissolving more than was shown in this three-day bottle test, it would still only disturb the total extraction on our ore to the extent of 26c. per ton. It is more than probable, however, that this residual 5% of the gold in the concentrate was not all "coarse gold," but largely gold intimately associated with the sulphides.

With a battery head of \$8 or \$10 gold per ton the residue from the sand-vats will assay in gold as follows:

Mesh.	Cents.
+ 60.....	80
- 60 + 80.....	70
- 80 + 100.....	50
- 100 + 150.....	40
- 150 + 200.....	40
- 200.....	60
Slime.....	40

These assays would tend to show that "coarse gold" is not the most serious of the problems we have to solve at this mine.

E. M. HAMILTON.

Torres, Sonora, October 8.

The Roasting of Telluride Ores.—II.

Contributed to the MINING AND SCIENTIFIC PRESS
By R. L. MACK and G. H. SCIBIDD.*

The average cost of roasting average telluride ores is 89 cents per ton. Of this cost 40c. is fuel expense. At this time no practicable method has been discovered for the treatment of telluride ores without a preliminary roasting.

EXPERIMENTAL ROASTING.

The method used was as follows: In order to ascertain, if possible, the amount of gold lost by dusting and volatilization of the tellurium it was necessary to weigh out $\frac{1}{2}$ A. T. of each of the various sizes. Fine samples of each size were weighed, placed in $3\frac{1}{2}$ -in. scorifiers, and arranged in the reverberatory furnace. Four of them

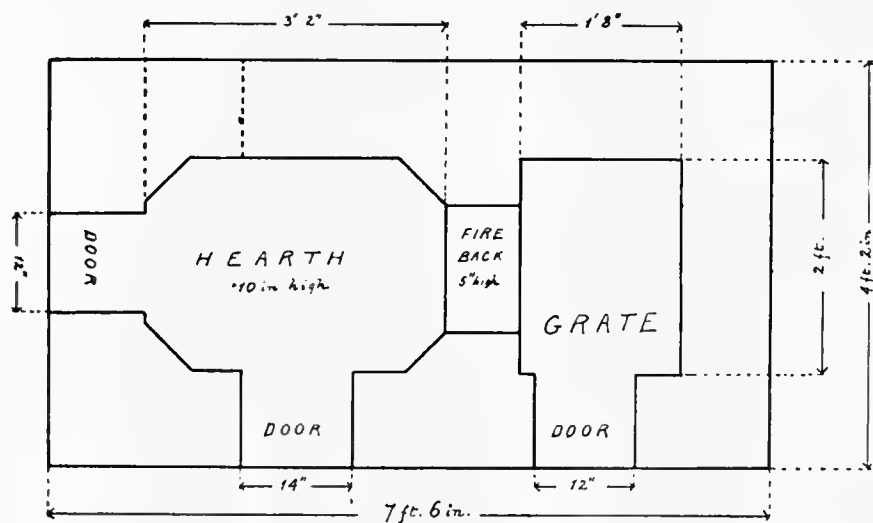

Fig. 1.

were to be used for assays of gold and silver, the fifth for a sulphur determination. By first assaying the raw ore and then assaying the roasted samples, the difference in the results would give the loss by dusting and volatilization. The process worked very well on the fine sizes, but not at all on the sizes coarser than 60 mesh, due primarily to the impossibility of obtaining an accurate sample, and secondarily to the difficulty of fusing the coarse ore. The necessity for weighing our samples before roasting them was due to the concentration resulting from driving off 3 to 4% of volatile substances. Several methods were tried to assay the coarse samples, but were not satisfactory. The best method is to grind them, after roasting, on a clean bucking-board, using the fluxes to clean the board after each grinding; however, even with the greatest care the results are not very satisfactory.

The concentration due to the driving off of sulphur and tellurium is nearly counterbalanced by the oxidation of Fe to Fe_2O_3 , but there is an unknown amount of concentration, which must be taken into account. Three separate roasts were made in the manner previously described; assays were run for gold, silver, and sulphur, before and after roasting.

TEMPERATURE DETERMINATIONS.

In our first tests we used a Chatelier pyrometer with a thermo-couple of one platinum wire and one wire composed of an alloy of platinum and 10% of rhodium. This couple was introduced into the reverberatory furnace at the flue end, as shown in the sketch. It was encased in $\frac{3}{4}$ -in. gas-pipe, plugged and capped on the inner end,

which enclosed a fused silica tube. The silica tube, sealed at the inner end, contained in turn, a double-bored fire-clay tube, through which the wires of the couple were drawn. These precautions were necessary in order to prevent any possibility of the furnace gases coming in contact with the couple, as platinum has the property of absorbing reducing gases, which reduce the slight amounts of impurities present in the platinum and cause a change in the electro-motive force of the couple.

By the use of such a couple only average temperatures in the furnace could be obtained, as the couple did not readily enough respond to changes in temperature, and also, due to its position, temperatures in other parts of the furnace could not be read. As it was desirable to read the temperature of each scorifier in the furnace a Fery radiation pyrometer was secured, which made possible the reading of the temperature

of each scorifier in the furnace at frequent intervals. Thus the best conditions for elimination of the sulphur, and consequently of the iron also, could be determined. The Fery pyrometer depends in its action upon the law of Stefan and Boltzmann, which is that the heat radiated by any heated body is proportional to the fourth power of its absolute temperature. In order to make use of the facts underlying this law, a concave metallic mirror is used to focus the heat waves radiating from the heated body upon the junction of a copper constantan couple. The electro-motive force generated by the action of the heat on the dissimilar wires is recorded on a galvanometer, so calibrated as to read degrees as

well as millivolts. The mirror and junction are housed in a metallic cylinder, so supported on a telescopic adjustable tripod as to have freedom of motion about a vertical axis. Focusing of the pyrometer is done by means of a thumb-screw, which causes the two halves of the inserted image to come into coincidence on either

Fig. 2.

side of a horizontal cross-wire. The furnace used was of the reverberatory type, as shown in the accompanying sketch. (Fig. 1.) Sketches are also appended to show the arrangement of the samples on the hearth during the roasts. (Fig. 2.) Also tables of temperature and curves to illustrate the variation of the temperatures.

PRELIMINARY ROAST.—A preliminary roast was first conducted as follows: A bed of ore about three inches deep was placed on the hearth, the furnace having been previously heated. As the temperature was raised, samples were taken at intervals of 20 minutes. The ore was well rabbled as the roast proceeded. The temperature was not sufficient to drive off all the sulphur, but the results obtained serve to show the rate of sulphur elimination. The original sulphur content was 3.08% and the final content was 1.02%. This shows that probably the temperature was only sufficient to drive off the first atom

*Submitted in partial fulfillment of the requirements for the degree of Bachelor of Science in Mining Engineering, under the Faculty of Engineering of Colorado College.

of sulphur, and the FeSO_4 formed was not disassociated:

Sample	Sulphur.		Minutes.
	Original	3.08%	
1	1.28	20
2	1.03	40
3	1.02	60
4	1.02	80
5	1.02	100
6	1.02	120

The above table shows the sulphur content and the rate of elimination. It shows that the greater part of the sul-

Fig. 3.

phur is driven off in the first part of the roast, and that to complete the sulphur elimination a much higher temperature is required. The curve appended shows this more readily.

Roast No. 1.—Three samples of each size were weighed and placed in 3½-in. scorifiers. The furnace was heated and the samples arranged on the hearth as shown in the following diagram: (Fig. 4.)

There was such a small percentage of sizes 80, 100, 120, and 150 mesh that they were combined. The heat was steadily increased over a period of 2½ hours, the temperature as indicated by the couple was read at intervals

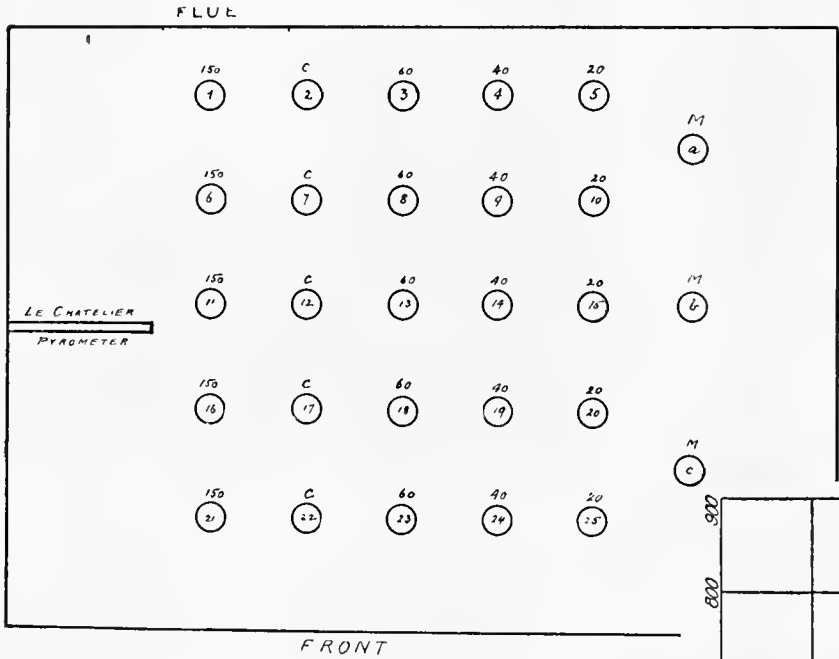

Fig. 4.

of 15 min. during the roast. The following table and curve show the results of this roast. The temperatures are given in both Centigrade and Fahrenheit degrees:

ROAST NO. 1.			
MESH.	Sulphur percentage.		Eliminated, %.
	Original.	Roasted.	
20	2.61	0.336	86.9
40	2.47	0.281	88.7
60	2.62	0.212	91.9
80 to 150	3.04	0.201	93.4
Through 150	3.93	0.116	96.9

Fig. 5.

This table shows that the fine contains a higher percentage of sulphur than the coarse; also that the sulphur elimination is best in the fine. The temperatures employed to effect the best sulphur elimination were, starting at 496° C (925° F), to raise slowly to 837° C (1,539° F). Time required was 1 hr. 45 min. for a small sample.

Time.....	Interval, minutes.	Deflection.	Gold Junction.	Temperature.			Remarks.
				Degrees C.	Degrees C.	Degrees F.	
3:00	40.0	19	536	997		Started roast at 3 hr. 19 min. 7 sec.
3:16	16	36.3		496	925		
3:32	16	42.8		560	1,040		
3:46	14	45.1		585	1,085		Reached 804° C during this interval.
4:02	16	47.1	21	607	1,125		
4:16	14	63.0		766	1,411		
4:32	16	63.2		768	1,414		Allowed furnace to cool down.
4:45	13	65.7	25	792	1,458		
5:00	15	63.9		837	1,539		
5:15	15	69.0		826	1,519		
5:30	15	60.5	26.5	714	1,317		
5:47	17	41.5		550	1,022		

Roast No. 2.—This roast was conducted just as in the previous experiment, except that the arrangement of the various sizes in the furnace was different. In the first case the fine was in the hottest part of the furnace, while in this roast the coarse occupied the hottest place. As shown by the table, the temperature at starting was higher and the maximum temperature obtained was not so great. The range of temperature was 546° C (1,015° F) to 799° C (1,470° F). The best sulphur elimination was obtained on 20-mesh size, due to the

Fig. 6.

fact that it was the hottest part of the furnace.

Roast No. 3.—In this experiment the temperature determinations were more complete than in either of the previous ones. Both the Fery and the thermo-couple were used to determine the temperature. The thermo-couple alone gives the temperature of only a part of the furnace, while by the use of the Fery, the temperature of the individual scorifier can be determined. Five samples of each size were placed in the furnace, in the positions shown in the accompanying sketch (Fig. 8); also three other scorifiers, in each of which was a quantity of the ore as it came from the rolls, being a fineness of about 14-mesh. These last three were to determine the point at which the ore frits. They were placed in the hottest part of the furnace near the fire-back.

The method of getting the temperature was as follows: The Fery was set up in front of the door, as shown in Fig. 4, and then the temperature as determined by the thermo-couple, which was inserted at the flue end of the furnace was recorded, after which the side door was opened and the temperature of the various scorifiers was read and recorded. At the end of the readings, the couple temperature was again recorded, thus showing the amount of cooling (due to the opening of the side door) during the reading. In this way the best temperature to give the best sulphur elimination could be ascertained; also the distribution of the heat over the furnace hearth could be noted.

The following tables and curve show the results of roast No. 3:

Fig. 7.

THE LOSS BY DUSTING AND VOLATILIZATION.

The assays of the various samples of roasted and unroasted ore were run under as nearly identical conditions as possible. Both scorification and crucible assays were used. The following table shows part of the results of these assays:

Mesh.	Sulphur percentage.				Gold assay.		
	Original.	Roast.	Soluble.	Eliminated.	Original.	Roast.	Loss in Gold.
20	2.61	0.18	0.11	93.1	1.40		
40	2.47	0.10	0.08	95.9	0.96		
60	2.62	0.12	0.09	95.4	1.37	1.34	0.03
Combined	3.04	0.12	0.09	92.9	1.49	1.46	0.03
Through 150	3.93	0.21	0.15	94.6	1.57	1.54	0.03

Through 150.	Oz. 1.57	Oz. 1.51	Oz. 0.03	1.92	Mean of four.
Combined.....	1.49	1.46	0.03	2.01	" " "
60.....	1.37	1.34	0.03	2.19	" " "

This shows a mean loss of 2.04% of the original gold content. As the roasting was done in scorifiers and a very thin bed naturally resulted, no rabbling was necessary. Therefore, the loss due to dusting was only that caused by the escape of the volatile gases. The determination of the amount of loss due, respectively, to dusting and volatilization is a problem in itself. However, it seems likely, having regard to the temperatures at which these roasts were conducted, that most of the loss is due to dusting.*

The highest temperature used on these roasts was 1,065° C. The mixed sizes of ore in the three test scorifiers fritted at 1,095° C. It is claimed that there is no loss of gold due to volatilization below 1,100° C.† The distribution of temperatures in the furnace as given by the Fery pyrometer is shown below:

Fig. 8.

As would be expected, the highest temperature is near the fire-box, the coldest part near the flue.

MODERN PRACTICE IN THE ROASTING OF TELLURIDE ORES.

By means of the Fery pyrometer we are enabled to read the temperature employed in one of the more prominent mills for the roasting of telluride ores. The furnaces were of the Pearce and Holthoff types. The Pearce furnace is an annular stationary hearth, with moving water-cooled rabblies, having four fire-boxes distributed around the outer circumference. Bituminous coal is used as fuel, the draught being increased by a jet of steam blown through the grate. The fire-boxes are not placed at equal intervals around the furnace, but are arranged about as follows:

- From flue to first fire-box is about 65 ft.
- " box 1 to box 2 " " 40 "
- " " 2 " 3 " " 30 "
- " " 3 " 4 " " 20 "

The flame travels counter clockwise around the annular hearth, while the ore (which is fed in near the flue) travels clockwise, thus moving from the coolest to the hottest part of the furnace, the discharge being about 20 ft. beyond the last fire-box. A chart is appended to show the various positions taken during the reading of the temperatures and the table shows the result of the reading:

READINGS AT POSITION No. 1. 22 FT. FROM FLUE TOWARD BOX 1.

The second furnace from which temperatures were taken was a Holthoff. This differs from the Pearce in having a movable hearth with stationary rabblies, the

gases being supplied from a producer in the centre of the furnace. The flame travels directly across the hearth in a radial direction to a series of small flues, which lead to the main flue. The ore, fed at the circumference, travels toward the inside of the hearth, where it is finally discharged to the cooling-hearth below. The following chart shows the positions from which the readings were taken and the table shows the results of the readings:

CONCLUSIONS.

From the results of our tests on small samples of ore of various degrees of fineness, we are led to conclude that:

1. The degree of fineness, if it is under 14-mesh, does not appreciably affect the amount of desulphurization, the important factor being high temperature with a sufficient amount of air.

2. The actual loss of gold by dusting and (possibly) volatilization was the same for sizes through 150-mesh to 60-mesh inclusive, but the percentage loss was slightly greater for the coarse sizes.

3. The average percentage loss was 2.04%. This

Fig. 10. Chart Showing Positions of Readings on the Holthoff Furnace.

would probably not hold exactly in practice, because in the mills the flue-dust is recovered and re-treated.

4. Sulphur is eliminated equally as well by using a high first temperature as by using a low first temperature, but loss by dusting is increased.

5. The object in roasting is not the elimination of sulphur, but of tellurium, the elimination of sulphur being an indication that tellurium is also eliminated. There is no practicable method for the determination of tellurium in works practice.

6. Calaverite melts at 365° C (689° F). If the telluride is present in large pieces due to coarse crushing of the ore, shattering of the gold results at temperatures from 550° C (1,031° F) to 1,064° C (1,917° F), the latter being the melting point of gold. Advantage is taken of this fact in the process worked out by Sutherland and Marriner, in which the shot gold is caught on amalgamated plates.

7. That this telluride ore, which is representative of the Cripple Creek district, crushed to go through a 14-mesh screen will be fritted at a temperature of 1,095° C (2,000 F).

Finally, we wish to express our obligation to Thomas T. Read, professor of mining and metallurgy, who directed the work of the investigation, to the Portland

Gold Mining Co., for the gift of the ore for the experimental work, and to G. M. Taylor, superintendent, and J. M. Tippet, metallurgist, of the company for valuable suggestions and assistance during the progress of the work.

BRITISH MINING.—The total number of persons employed in and about all the mines of the United Kingdom in 1906 was 912,576, of whom 882,345 worked at the 3,278 mines under the Coal Mines Act and 30,231 at the 715 mines under the Metalliferous Mines Act. Compared with 1905, there was an increase of 23,972 persons at the former and of 1,080 persons at the latter. At the coal mines 80% worked below ground, while of the surface workers 3.16% were females. The total output of minerals under the Coal Mines Act was 265,204,716 tons, an average per underground employee of 374 tons, an increase of 13 tons on the preceding year. Of the production, 251,050,809 tons were coal, 2,971,173 fire clay, 8,209,880 tons ironstone, 2,546,113 tons oil shale, and 426,741 tons sundry minerals. Adding 16,819 tons from open quarries, the total output of coal was 251,068,628 tons, which is an increase of 14,938,692 tons on that of the previous year. The total output under the Metalliferous Mines Act was 3,712,436 tons, of which 1,824,415 tons were iron ore. The total quantity of stone and other minerals obtained from the quarries under the Quarries Act was 46,985,443 tons, of which 4,410,291 tons were iron ore. Adding to the produce of mines and of quarries over 20 ft. deep 1,055,820 tons obtained from shallow open workings, there was a total output of iron ore of 15,500,406 tons. The death rate of the underground workers under the Coal Mines Act was 1.42 per thousand persons employed, against 1.49 in 1905. The death rate in the metalliferous mines of the underground workers was 1.63 per thousand persons.

AN UNDERGROUND ELECTRIC FORGE.—The Village Deep Mine, in the Transvaal, is installing a newly invented electric furnace for underground use in drill sharpening. Should it prove successful the direct economies resulting from its general use will be considerable, as it will overcome the difficulties of overheating and burning the steel and obviate the expense, labor, and delay of carrying the drills to the surface every time they require sharpening. The initial tests are being carried out at the surface, and subsequently lengthy and rigid tests will be made underground, and if the results come up to expectations, then one furnace will be supplied to every three levels. This furnace, if the success expected is realized, will have a far-reaching effect upon working costs at the Rand mines. Several managers have already stated that they now use steel of a medium quality in preference to the best steel, for the reason that under the present system of heating the best steel is often burnt, and is invariably reduced to the quality of poorer steels. The latter, on the other hand, are found to suffer no corresponding falling off in quality. This practice, which is by no means general, may largely account for the complaints made regarding faulty steels. Should this furnace prove the success indicated, then the best steel only should be used, with the results that fewer complaints will be made about the blunting of the drills. Certainly much more attention ought to be given to the important questions of tempering and sharpening drills, not merely in the Rand mines but also in other mining fields.

THE COPPER ORES of the Copper River district of Alaska occur along the contact between a semi-crystalline limestone and a greenstone; the greenstone is probably an ancient lava-flow.

The Tyee Smelter.

Written for the MINING AND SCIENTIFIC PRESS
By RALPH L. PHELPS.

To reach the reduction works of the Tyee Copper Co., Ltd., at Ladysmith, on Vancouver Island, the traveler leaves Victoria at 9 o'clock in the morning on the daily passenger train of the Esquimalt & Nanaimo Railway, which connects Victoria with Ladysmith and Wellington, the last being the terminus in the coal mining districts. This local line is owned by the Canadian Pacific Railway, and though running through productive agricultural valleys and important mining districts, despatches but one train each day simultaneously from each end of the line. With good luck and perseverance on the part of the engineers, the toy Baldwin engines manage to pull these trains the 77 miles in about 4 hours, when on time. But the delightful country and scenic beauty of the interior of Vancouver Island reward the traveler amply for the tediousness of the journey. The general

which will run out for about 400 ft. into deep water. On this wharf there will be erected one 300-ton stationary bunker and one 60-ton movable bunker. The reason for having a movable bunker is to allow the unloading of any two hatches in a ship at one time. On the top of these bunkers there will be an electrical hoist, capable of handling 30 tons per hour. The ore from these bunkers will be run into 2-ton side-discharging cars. The intention is to work three sets of cars, each set containing five cars. While one set is being loaded one set is being dumped, and the third set is on the way between the wharf and the storage bunkers, which are connected by an incline 1,200 ft. long. The train of cars is hauled up this incline by means of a large hoisting engine. As soon as a train of cars reaches the top of the incline an electric locomotive hooks on and they are run over a 40-ft. platform-scale with self-registering beam. After being weighed, part of each train is switched to the sample-bin and the remainder run to the storage-bunkers. These bunkers will have a capacity of 5,000 tons. The new

equipment will be electrically operated and power for this work will be supplied by a new steam-driven generator, recently ordered from the Allis-Chalmers-Bullock Co. This will effectually reduce the present cost of handling and also save considerable time. Coke is delivered at the smelter in 20-ton rack cars by the Wellington Colliery Company.

Formerly all the ore treated at this smelter was roasted in piles on a specially prepared yard, a description of which appeared in this paper, but at the present time no roasting is done and the old roast-yard is used for the storage of ore. The sampling mill is of the latest design and has a capacity of from 30 to 40 tons per hour. The building is shown on the extreme left in the photograph.

The present furnace equipment consists of one 200-ton Allis-

Chalmers water-jacketed furnace, 42 by 120 in. with a 10-ft. ore column. The ordinary capacity of this furnace is about 200 tons per day, but at the Tyee plant they are successfully smelting from 250 to 300 tons per 24 hours with a blast-pressure of between $1\frac{1}{2}$ and 2 pounds. The furnace is fed by hand from both sides simultaneously. The blower-equipment consists of an Allis-Chalmers Corliss engine, belt-connected to a No. 7 Connersville blower.

The slag and matte from the furnace flow over a water-jacketed bronze spout and drop into a settler, which has been designed and perfected by Mr. Watson. This settler has proved highly efficient. Designed on lines similar to the commonly, though erroneously called, 'syphon' settler, Mr. Watson describes it as a matte separating fore-hearth. A photograph is shown herewith. This water-jacketed fore-hearth is 10 ft. long, 4 ft. deep, and lined with $4\frac{1}{2}$ in. fire-brick. If, by any chance, the pocket should 'freeze', it can be taken off, the brick and chilled matte barred, and a new lining built in. By carefully drilling a hole through the frozen connection, so as not to disturb the settler lining, it can be started again without interfering with the running of the furnace. While this is taking place the settler is tapped in the usual way through a bronze tapping-jacket, which is used for emptying the settler when blow-

The Tyee Smelter.

offices of the Tyee Copper Co., and the residence of the general manager are at Duncans station, 40 miles from Victoria, and the mine itself being situated in the mountains 5 miles from Duncans. The reduction works are situated at Ladysmith, on Oyster bay, an inlet of the Gulf of Georgia, on the east side of the Island. W. J. Watson is the manager of the smelter.

The ore from the Tyee mine is brought down to the railroad by a Riblet aerial tramway, $3\frac{1}{2}$ miles long, having a drop from the mine of 1,700 ft. The ore is here automatically dumped into storage bins on spur tracks and hauled by train to the bins at the smelter. As the tonnage capacity of the smelter is greater than the present daily output of the mine, Mr. Watson is handling a large proportion of custom ore as well. Owing to the advantage of being situated on deep water, the works receive copper ore from the Snowstorm mine in Idaho, from Prince of Wales island, and the British Columbia coast; gold ore from White Horse in the Yukon; and silver ores from Mexico.

At the present time all ore coming by the sea is unloaded at the Dunsuir wharf at Ladysmith into hopper-bottom cars and thence switched to the smelter bins, distant one mile. This method of handling the ore will be greatly improved upon, as the company is at present pushing work on the construction of their own wharf,

ing out the furnace. The hole connecting the pocket with the settler is 4 by 6 in. and is lined with chrome brick. The matte spout on the pocket is about three inches lower than the slag spout on the settler. The flow of matte is regulated by manipulating the slag outlet. If not sufficient matte is running, the slag outlet is raised slightly by pressing in a small ball of clay on the point of a rod; if too much matte is running, the slag outlet is opened a little. The depth of matte in the settler is ascertained every hour, and as near as possible 8 or 10 in. of matte is kept in the bottom. This settler has been used successfully for over two years and the difference in the slag contents more than paid for it in one month, besides doing away in a great measure with the possibility of men being burned. There is also a considerable saving in pots and clay. At works where the matte is not tapped for immediate converting, the settler would be invaluable, and doubly so where a large quantity of low-grade matte is made. The Tyee ore runs about 4% copper and a 40% matte is produced. The

and settler-attendants are either Americans or Englishmen, as the work requires more skill. Three 8-hour shifts operate the furnace and the wage paid for this work ranges from \$3 to \$4.25 per day. It is interesting to note that English and American carpenters receive \$4.25 for 8 hours work and their helpers receive \$3. They begin work in the morning at 7 o'clock and stop at 4 in the afternoon. This seems a high wage for such skilled labor and it appears odd to an American to see men stop work so early in the afternoon.

The town of Ladysmith is the home of hundreds of miners employed in the near-by coal mines. Presenting an almost deserted appearance during the day, it becomes animated with the arrival and departure of the coal miners trains, which makes the run between Ladysmith and the adjacent mines at the end of each shift. With one main business street of several blocks, Ladysmith boasts a good commercial hotel and the inevitable branch of the Canadian Bank of Commerce. The writer is under obligations to the late Clermont Livingston, to W. J.

The Watson Fore-Hearth.

matte is run into conical pots, which are of standard wheel-body construction. When filled, they are wheeled to the cooling-floor; later, the matte is broken up for shipment to the Tacoma refinery.

The disposal of the slag at Ladysmith is effected in an economical manner. The molten slag from the settler is led directly into water-flushed launders, where it is granulated and carried 400 yards into the bay. Use of the slag is made in filling in a shallow arm of the bay near the smelter, for future yard-room. As the slag enters the launder and comes in contact with the water, fumes of sulphuretted hydrogen are given off, due to the decomposition of a small percentage of barium sulphide in the slag.

In the disposal of the flue-dust, the practice is to wet it down thoroughly and feed directly into the furnace.

The cost of coke delivered at the different smelters on Vancouver Island is about \$7.50 per ton. The labor employed in handling the ore and coke in the yards is principally Chinese and Japanese. These laborers receive from \$1.75 to \$2 per day for 10 hours. The furnace-men

Watson, G. B. Kitto (Mr. Watson's assistant), and George Williams (who is superintending the construction work) for many courtesies and for valuable information.

MEASURING MASONRY.—It is customary to measure all foundation and dimension stone by the cubic foot. In stone work corners of buildings are measured twice, and arches are counted solid from their spring. One cord of rough stone, three bushels of lime, and one cubic yard of sand will lay 100 cu. ft. of wall. When suitable stone cannot be found for engine foundations, concrete composed of one part of No. 1 portland cement, two parts coarse sand, and five parts of stone, broken to the size of egg coal; coarse gravel may be substituted for stone. Turn and mix while dry, twice. Turn and mix with water twice, and place. If the concrete is to be richer, use more cement. Brickwork is usually measured by the 1,000 brick laid in the wall. In consequence of the variations in the size of common brick, no rule for volume of laid brick can be exact.

The History of Gold and Silver.

By JAMES W. MALCOLMSON.

*The history of gold and silver to a large degree is the history of civilization. These metals have been found in all countries of the world and are widely diffused throughout the crust of the earth. In the earlier ages of the world, gold was obtained more readily than silver, as it is not affected by oxidation or decay. On account of its weight, it settles in the metallic state in streams to the bedrock, and on account of its resistance to natural leaching processes, it is often found at the outcrops of mineral deposits where all other minerals have disappeared entirely.

Silver, on the other hand, is but seldom found in the metallic state, but is more often mixed with gold, lead, copper, or zinc. Pure silver minerals, such as the chloride or sulphide, are almost as rare as native silver, and silver ores are usually complex mixtures in which other metals predominate. The processes of treatment of silver ores are therefore more complex than those of gold, and the metal is only obtained by regular underground mining operations, as it is but rarely carried far away from the zone of its original deposition.

It is probable that gold was employed long before silver was known, and the value of silver in some ancient states appears to have been superior to that of gold. Even in Japan, up to the seventeenth century, the value of gold and silver were almost equal. Soon after the first opening of that country to commerce, the Dutch secured nearly all the gold of Japan in exchange for silver, before the Japanese learned the difference in values in Europe.

In ancient Greece in the days of Herodotus, gold was thirteen times more valuable than silver and this ratio appears to have been fairly constant for many centuries. For nearly 1,000 years, to the fall of Constantinople, the ratio of value of gold to silver in the Roman Empire was approximately 12 to 1. In Arabia, in the sixth century, the ratio was 6½ to 1, while at the same time it was 10 to 1 in France.

In Spain in 1493 it was 10½ to 1.

In 1500 the ratio of value of gold to silver was 10½ to 1.

In 1600 it was 12 to 1.

In 1700 it was 15 to 1.

In 1800 it was 15½ to 1.

In 1900 it was 33½ to 1, probably on account of its demonetization throughout nearly the whole of Europe and America.

It was a remarkable fact that from 1660 to 1860, a period of 200 years, the ratio of the value of gold and silver remained almost stationary at 15½ to 1.

The search for gold has been the first cause of the settlement of much of the earth's surface by civilized races. Del Mar believes that the Argonauts, who sailed from Thessaly with Jason to obtain the golden fleece in Colchis, were probably leaders in a rush to new goldfields or placer deposits along one of the rivers flowing into the Black Sea. The allusion to the golden fleece perhaps indicates the use of sheep-skins in sluice-boxes in the way that we still use woolen blankets for the same purpose.

The settlement of Egypt by the Semitic races of Asia has been thought to have been contemporaneous with the first discovery of the gold mines of the peninsula of Sinai more than 2,500 years before Christ and the Phœnicians and Jews, the kinsmen of these hardy pioneers, went out and searched the whole world for minerals. In the Book of Job, supposed to have been written 1,500 years before

Christ, a notable reference to gold and silver occurs, as follows: "Surely there is a vein for the silver and a place for gold where they find it, as for the earth, the stones of of it are the place of sapphires and it hath dust of gold." Of Solomon, who lived 1000 B. C., it was said that "All his drinking vessels and all the vessels of his house were of gold, none were of silver, it was nothing accounted of in the days of Solomon." It is a curious fact in the history of mining, that no matter how intelligent or economical a man may be, if he be unsuccessful in finding ore, his industry and talent count for nothing; and no matter how imprudent or unintelligent he may really be, if he finds rich ore and makes a high profit, he is hailed everywhere as wisdom personified. It was probable that something of this sort happened to Solomon, and since then his mines have been the theme of the novelist and poet. He was closely allied with both the Egyptians and the Phœnicians; he married Pharaoh's daughter and was a close friend and ally of Hiram of Tyre, King of Phœnicia. On account of his success in gold mining in Africa, in Egypt, and elsewhere, it is probable that every wise saying for centuries was attributed to him. Even his matrimonial adventures are more or less characteristic of many successful mining operators of our own time. In southwestern Africa, over an area of 600 miles square, the ruins of fortified cities and great mining camps are found, about which almost nothing is known today, except that the occupation of the ancient inhabitants was gold mining. It is estimated that over \$400,000,000 of gold was extracted from these mines.

Andrew Lang says of them:

"Into the darkness whence they came, they passed,
Their country knoweth none;
They and their goods without a name
Partake the same oblivion
Their work they did, their work is done
Whose gold it may be shone like fire,
About the brows of Solomon
And in the House of God's desire.
We know but that men fought and fell
Like us, like us, for love of gold."

The silver mines of Laurium, 30 miles west of Athens, were worked for centuries by the Greeks and are referred to by Tacitus, Aristotle, and many other writers. They seem to have been worked originally by the Phœnicians in 1200 B. C. Demetrius, a Greek writer, who lived 300 B. C., boasted that the Greeks worked these properties with such energy that they threatened to dig up the devil himself. Shortly after this period, mining operations ceased. The mines of Laurium were reopened successfully by the French in 1860 and are paying dividends at the present time.

In the search for gold, the Phœnicians, and afterward the Romans, who were more skillful miners than the Greeks, were led to Spain, which was to the ancient world what Mexico is to us today, but, during the most critical period of the Punic wars, Rome debased its silver money and demonitized its copper coinage, because the silver and copper supplies of the world at that time came from Spain, then in possession of the Carthaginian army. Hannibal, however, had other resources, and this became, probably, the first great war in history where the troops of both armies were paid in gold coin.

In the fourth century the Romans worked gold mines in every province of Europe, and practically all the gold known at that time was in their possession. Humboldt is authority for the statement that America was discovered because Columbus sought a nearer way to the gold mines of Japan, while Cortez and Pizarro penetrated the unknown forests of the New World in search for the precious metals. The conquest of India and South Africa, the settlement of California, Australia, and Alaska, all

*A paper read before the American Mining Congress at Joplin in November, 1907.

originated in the desire to obtain golden treasure, and the search for gold has carried the torch of civilization throughout the world. It is a curious fact, however, that the English-speaking people alone produce today nearly seven-eighths of the world's production of gold.

Asia possesses a remarkable capacity for the absorption of gold and silver and much of the precious metals sent there seems to be permanently withdrawn from the stocks available for money. It may be that much of this is hoarded or buried in the ground and lost, becoming practically non-existent. Asia has been called the sink of gold and silver, and its ability to absorb and lose these metals has been a subject of remark ever since the time of Alexander the Great.

Among all civilized peoples, gold and silver have derived their chief importance from their use as money. In the earlier period, the first money in use among undeveloped or isolated communities consisted of skins, salt, shells, soap, slaves, cattle, sheep, olive oil, tobacco, iron, tin, lead, copper, nickel, and platinum. In such communities transportation facilities were rudimentary, commercial operations were limited to small areas and carried forward slowly on a small scale. Money has been defined as that which passes from hand to hand throughout the community in final discharge of debts and as full payment for commodities or service, being accepted without reference to the character or credit of the person who offers it.

For many reasons, the metals finally superseded all other forms of money, and gold is gradually displacing all other metals and driving them from the field. Cattle die, iron rusts, slaves grow old, but gold and silver, and more especially gold, fulfills all the requirements of money better than anything else. Gold is of small volume compared with its weight and value; it is of uniform quality, easy of transport, easily guarded, readily divided and reunited without loss. Its identity is perfect, it is easily recognized and is beautiful, brilliant, and durable almost to eternity. It is probable that gold which was in use at the time of Solomon is in active service still. Gold does not deteriorate with storage or time and its firm and compact texture makes it difficult to wear away.

Until within the last generation, the value of gold bore practically no relation to its cost of production, but depended only on the total quantity in the hands of mankind. For ages its value changed only by slow degrees. In ancient times, strong nations plundered weaker races of their hoards of the precious metals and more modern powers have followed their example, using it without regard to the cost of production. It is probable that gold and silver were used as money long before the metals were stamped and coined and this was ultimately done in order to save the trouble of weighing and assaying for each transaction. The talent, shekel, etc., in the Hebrew records, all refer to the use of money by weight, while the English pound and the Spanish *peso* and *onza* all indicate weight. The word coin itself, meaning a wedge, indicates a primitive method of using money. Our word pecuniary, now applied to metallic money, originally meant cattle, and from the custom of counting cattle comes our present designation of money as capital, meaning heads.

The coinage of gold and silver was adopted at first by private individuals and cities to guarantee originally the fineness and afterward both the weight and purity of the metals. In Rome, under the Empire, however, coinage became the exclusive privilege of the Emperor. Herodotus attributes the first use of coined gold and silver to the Lydians, but it is probable that the real date was much earlier. As civilization advanced, the use of

gold and silver as money became a modification and improvement on the earlier methods of simple barter, and gold presented us with a desirable standard of comparison with which all other values, even including future obligations, are compared and measured.

Gold, however, is not absolute standard, such as the pound weight or the metre length, but is simply a relative measure of value as steady as anything we have. In other words, it is possible for gold itself to change in value. The control of weights and measures has always been one of the great functions of governments and is one of the necessary prerogatives of national life and honor, and every honest government since the dawn of history has protected the use of gold and silver with the best guarantees it could devise, both as regards its weight and its purity. The reputation of any government can be more readily and more seriously injured by the defects or debasement of its currency than in any other way. Changes in the value of gold are reflected immediately in the price of some commodities and very slowly in the price of others, particularly in wages and returns from investments bearing a fixed rate of interest. In any change in the value of gold, the poorer portion of the community suffers most; employers and merchants are quick to discount any change, and they adjust themselves to new conditions more readily than the wage-earning classes. Those living on the interest paid on bonds or mortgages cannot adjust themselves to the change at all, and are paid a fixed amount of gold, irrespective of its value. The wealth stored up by all communities in interest-bearing bonds, using gold as a fixed standard for future payments, is affected enormously by changes in the value of gold and the result of such changes on the business commerce of the world is hard to realize.

Although gold is mentioned in the early literature of every race, it is difficult to learn its ancient value as measured in terms of food and wages. It is certain, however, that its value in early times was a thousand times greater than it is today and that this value had been decreasing slowly until the discovery of America. In the thirteenth century, it was estimated that the total stock of gold and silver in Europe was approximately \$6 per capita, the population at that time being 30,000,000. Only one-half of this gold and silver was coined; no banks or negotiable paper existed. Good roads were few and there was little peace and no credit. From the fifteenth to the eighteenth centuries enormous quantities of silver were obtained by Europe from the New World and the gold supplies of Japan and India were gradually transferred to Europe until, by the end of the eighteenth century, there was estimated to be ten times as much of the precious metals in Europe as in the thirteenth century. As before mentioned, previous to the eighteenth century, the value of gold bore practically no relation to its cost of production, but depended primarily on its peculiar fitness for money as a basis of value and on the total amount in use. Before 1840, the annual production of gold bore such a small relation to the total quantity existing, that its cost of production from year to year never materially affected the value of the whole quantity in use, and Humboldt, in a remarkable article on the production of gold, written in the early part of the nineteenth century, predicted that these conditions would exist for all times.

In 1845 the annual production of gold in Russia increased very largely and all Europe was alarmed. In Holland, the desirability of a single silver standard was widely discussed. In the Netherlands, gold was demonetized in 1847 and the silver florin declared to be the sole legal tender. Belgium soon followed suit. In 1847 a run occurred on the Bank of England. In 1848 the Bank of Austria stopped payment, and when in 1849 California

began to give its golden treasury to the world, the golden panic reached its height. In 1857 Russia suspended payments in specie, and the German States, including Austria, adopted a single silver standard. Chevalier advised the Government of France to demonetize gold and Cobden, in England, seriously recommended a return to barter. After this increased production of gold, however, the actual course of events reversed all predictions, prices rose everywhere, and the world entered upon a period of unexampled progress and prosperity, and in 1871 the German Empire finally adopted the gold standard and discontinued the mintage of silver, being followed in 1873 by the United States and France and by the Latin Union, Holland, and Belgium in 1875.

It is, however, owing to the utilization of the power of steam, during the past 50 years, a cause which has wrought so many changes in human affairs, that the use of gold as money has been almost completely revolutionized. The amount of gold in the world, which, before 1850, had increased slowly and had barely kept up with the increase in population, suddenly increased by leaps and bounds. It became twice as great, ten times as great, and by the year 1900 the annual production of gold became approximately 400 tons, or 22 times as great as in 1800. Since then the production has increased with equal rapidity, until now it has reached 680 tons per year, and it is estimated by competent authorities that in the next 16 or 17 years the amount of gold in the world will be doubled. In other words, the amount of gold which has taken the entire civilized world thousands of years to accumulate, will be doubled in our lifetime. In addition to this, the spread of knowledge, the development of railroad and ocean transportation, the use of the telegraph and the growth of modern banking methods, have all increased the efficiency of gold as money. This has also been aided by the greater confidence which races and individuals now have in each other, which is one of the great underlying features of modern civilization, and a golden dollar can be made to do more than a hundred dollars did a century ago. These rapid changes are being accompanied by others equally remarkable; money can now be transported throughout the world at a speed undreamt of by our fathers, cheaply and with almost perfect safety. It has been still further facilitated by international and other clearing-houses, where transactions involving the use of the measuring power of gold are affected to an enormous extent by telegraphic communication without actually moving or handling the gold itself at all. All this has tended to make gold cheaper. On the other hand, the enormous scale on which commercial enterprise is now being carried forward, the improved mode of living of whole races, the demands of industry for money along so many different lines, the money needed in the building up of new countries and the funds required for war purposes, all tend to keep up the price of gold.

Underlying all these activities, however, remains the commodity gold, upon which all our calculations are based and the fact must always be remembered that gold as money is only a measure of value by virtue of its relation to the value of other commodities. In all countries, apprehension is felt when gold is exported and this perhaps is an unconscious admission that the quantity of gold in any community exercises an important influence on its industries and its commerce. The use of gold as money is primarily a modification of the system of barter or exchange and is to a lesser degree than any other material human standard, a creation of law. At the same time it must be the effort of government to limit and define its use with precision.

In spite of the present efficiency of mining operations

and the improvements and economies in metallurgical processes, it is probable that the demands of industry and commerce which are increasing so enormously, will ultimately increase the value of gold, or at least prevent its depreciation to any serious extent below its present level. Whether the value of gold will change materially in the future or not, is a subject that deserves the earnest consideration of every statesman. Although this subject has received the attention of thinkers in all ages, the issues have usually been hidden by the personal interests of rulers, or of those controlling the supplies of the precious metals, or by the desire of governments to secure the greatest benefits for their own coinage. It is seldom that the people of any community have had the opportunity to investigate the relation of this question to their own welfare, and it is not improbable that some of the inequalities of our social system may be traced directly to this cause. The growth of organized society depends largely upon the development of exchange, and exchange is impossible without money. If we must continue to use gold, it is of prime importance that our government should be able to form an accurate judgment regarding its present and future value because this, the basis of our monetary system, fixes the value of much of the property in our own country over long periods of time.

A Chance to Get Rich.

[A friend at New York sends us the following copy of a letter received lately by him. To sell a mine "as a hole" does not usually "suit the buyer." Many a truth is conveyed by a misspelt word.—EDITOR.]

Dear Sir I see your ad in the Mining Press, now dew you ever handle enny mines fore sale, ifso I have some good gold mines In californnia, fore sale some with mashenry on them, and free milling ore, and the prise ranges from \$15,000 to \$250,000 also I have a good gold mine in Georga, free milling ore, and the oner was offered at one time \$150,000 cash fore the mine but sense that the oner has Died and now the widdo is offering the mine fore \$125,000 to make a Quick sale as she is getting old ond wants to settle up her buisness and retire, I also have 3 good copper mines In this state, one with 25 clames and the other with 30 now there is only the develope work done on them, the ledge shows on the serfas, 100 foot wide and about ¼ mile long and the prise is \$75,000 fore one and \$200,000 fore the other, now the oner will still keep a intres in the mine if the buyer dont want to buy out rite, ore he will sell as a hole to snit the buyer. now I will alow you a 5% commission on enny sale that you can make hoping that you can be able to dew some buisness I remain yours truly. awating your reply.

JOHN SMITH. Oakland.

THE REPUBLIC OF MEXICO, according to a statement published recently by the Mexican Department of Fomento, contains more than 1,000 mines operated mainly for copper production. These are located in the different States as follows: Jalisco, 302; Sonora, 234; Michoacan, 95; Lower California, 65; Chihuahua, 53; and Durango, 51. In proportion of production tonnage, however, Sonora leads, while Lower California is second; the mines in the State of Jalisco are small producers.

WHEN SHARPENING AND TEMPERING DRILLS leave the sets on the forge until all are finished, then heat the bits cherry red, but not the body of the steel; dip in clean water, moving slowly down, then out, leaving heat enough in the body of the drills to toughen the bits by starting temper to show color. Check color by cooling in the slack tub.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

PROCESS FOR EXTRACTING GOLD AND SILVER FROM ORES.—No. 871,766; Gilbert Gurney, Berkeley, California.

The process of extracting the values from sulphide ores, which consists in first subjecting at normal temperature and without pressure the raw ores to the action of a solution containing the higher or perchloride of a metal of two or more valences, together with a chloride of an alkali metal and a free mineral acid, and afterwards precipitating the values from the resultant solution.

ORE-CONCENTRATING TABLE.—No. 871,369; Alfred Schwarz, New York, New York.

A concentrating table having corrugations, said corrugations being sufficiently small in transverse section to create zones of liquid substantially quiescent in planes transverse to the corrugations, said zones being of sufficient extent to receive the metallic values and protect the same from transverse currents of wash liquid, means for differentially reciprocating the table, and means for supplying wash water thereto.

CONCENTRATOR.—No. 871,546; Calvin H. Wilkie, Douglas, Arizona.

In a concentrator, a tank comprising a bottom, a perforated diaphragm, and a shell suitably connected together, the diaphragm and bottom being separated to provide a pressure chamber, and the diaphragm and shell constituting together a separating chamber, said bottom having an impermeate tube rising therefrom, extending through, and supporting the central portion of the diaphragm, a shaft

extending through the tube, means connected with one end of the shaft for rotating the same, a cone fitted to the other end of the shaft, an agitating head rotative with the shank and located between the cone and tube, and agitating devices connected with the head and extending into said separating chamber.

FILTER-PRESS.—No. 872,008; Frederick W. von Oven, Aurora, Illinois.

In a filter-press, the filter frames having inlet-ports in the junctions between them, and provided with ears containing openings forming a feed-passage common to said ports. In a filter-press, a chamber forming element consisting of a frame comprising a rim having inwardly beveled edges and a flange affording shoulders extending about its inner edges, screens abutting against said shoulders, and an open-work flexible mat interposed between the screens, and filtering cloth covering the frame sides.

DEVICE FOR SEPARATING MATERIALS HELD IN SUSPENSION BY LIQUIDS.—No. 872,033; Charles N. Waite, Wilmington, Delaware.

In a separating device, the combination with a tank; of a screen dividing said tank; an inlet pipe for unseparated materials, arranged on one side of said screen; an outlet for separated residue arranged upon the same side of said screen; an outlet for strained liquid arranged on the opposite side of said screen; means for effecting the discharge of the separated residue; and means responsive to abnormal increase of pressure beneath the screen for actuating the controlling mechanism of said discharging means.

METHOD OF CONCENTRATING ORES.—No. 871,368; Alfred Schwarz, New York, New York.

The process of concentrating ores consisting in sizing the ore and flowing each size in a pulp current over bodies of liquid restrained from movement in places in the direction of gravital flow, inclosing the values in the quiescent liquids, and differentially agitating the whole to promote settling, and to convey the settled values in directions other than that of gravital flow, and gravitally washing away the gangue.

Carbons.

Written for the MINING AND SCIENTIFIC PRESS
By JACQUES BASZANGER.

The carbonado or black diamond is one of the hardest substances known, being sometimes harder than the crystallized diamond. It is, however, unsuitable for cutting into gems, because of its opacity, and its being amorphous. Carbonado was first successfully used by the French engineer, Lechot, in the drills for boring holes for blasting in the St. Gothard tunnel. At present carbonado is largely employed in diamond-drilling, in connection with which it is one of the principal items of cost.

Carbonado is obtained in the province of Bahia, Brazil, in La Chapad and Lavras districts, where it is mined from stream beds and other alluvion. The miners sell their finds to agents of exporting firms in the city of Bahia. Some very large stones have been found, among others one of 1,100 carats about 25 years ago; also one of 1,700 carats and in 1895 a gigantic stone of 3,078 carats, or 615 grams, which was sold by me. This stone was purchased for \$32,000; at the present time it would be worth about \$275,000. Several stones of 400 to 800 carats have been discovered during the last ten years, and stones of 100 to 200 carats are frequently found.

Previous to 1870, carbonado was practically valueless. From 1870 to 1872 it was employed as an abrasive for cutting and polishing the white gems, and thousands of carats were sold at 50 cents per carat, to be crushed into powder for this purpose. A few years later, when carbonado was employed in diamond-drilling, it sold at \$2 to \$4 per carat, and then rose gradually to \$10, at which price it remained until 1895, after which it advanced by leaps and bounds to \$50. The price fell back to \$25, but rose again to \$95 per carat, at which figure it now stands.

The high price now prevailing is due to the decline in the supply of carbonado during the last ten years, while the demand has increased. When diamond-drilling is resumed more extensively on the Rand, it is expected that it will be even more difficult to supply the demand for carbonado. Bearing upon this subject, it is interesting to remark that in putting down the drill-hole at Rybnik, in Upper Silesia, which attained a depth of nearly 7,000 ft., upward of \$25,000 worth of carbons was consumed. The carbon settings for a drill-bit are expensive. Bits as large as one foot in diameter, set with \$5,000 to \$8,000 worth of carbon, are frequently employed in Europe.

OCCURRENCE OF DIAMONDS.—Volcanic pipes in which diamonds are found are not peculiar to South Africa. Similar formations have been discovered in New Zealand and quite recently in Connecticut, but it is only in South Africa that the diamond deposits have attained any economic importance. The so-called pipes in which the diamonds are found may be considered to be the material filling the craters of extinct mud volcanoes. For a long time it was supposed that diamond mines were only to be found in the neighborhood of Kimberley and in the district farther to the east, in the Orange River Colony, where the Jagersfontein and Koffyfontein pipes are situated. Within the last few years, however, diamond pipes have been found in many other parts of the country, and among them may be mentioned the Premier, Montrose, and Schuller pipes near Pretoria, in the Transvaal; the Lace and New Randfontein Reefs pipes near Kroonstad, and the Victor pipe near Boshof, in the Orange River Colony; while the Peizer, New Weltrrede, and Frank Smith have been discovered to the northwest of Kimberley.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

While a miner, like other servants, was bound to take notice of patent defects in the entry of the mine where he was working, the law does not require him to make an examination for hidden defects, but he may assume that the owner or operator had used reasonable care not to endanger his position by other workings.

Superior Co. v. Kaiser, (Ill.) 82 Northeast, 239, Oct., '07.

The rule that a servant or a miner assumes the ordinary risks incident to the work in which he is engaged, is based on the supposition that the master has performed the duties of care, caution, and vigilance which the law places on him.

Superior Co. v. Kaiser, (Ill.) 82 Northeast, 239, Oct., '07.

The failure of the owner and manager of a mine to thoroughly examine and inspect the face of a certain cross-cut was held to constitute such negligence as to permit a miner to recover for injuries received while working in an entry near to such cross-cut, and that such cross-cut was developed in advance of and so close to the rib and face of the entry as to loosen, crack, and weaken the rib and face of such entry at the point where the miner was at work and where he was injured. Such miner was not charged with contributory negligence where the fall of coal which injured him was from the face of his entry, which, on examination, appeared to be safe on the morning of the accident.

Superior Co. v. Kaiser, (Ill.) 82 Northeast, 239, Oct., '07.

A contract by a mining corporation to issue stock to a certain person in payment for his services in aiding another to dispose of the stock of the corporation and in making assays was illegal under a constitution prohibiting any corporation from issuing stock except for labor done, or money or property actually received; and it was the duty of the court in an action on such contract to refuse to enforce it as against the corporation though the corporation failed to plead such illegality.

Rogers v. Gladiator Co., (S. Dak.) 103 Northwestern, 86, Aug., '07.

A deed granting all the oil and gas under a certain tract of land, with the exclusive right to enter at all times for the purpose of drilling and operating for oil and gas, but limiting the estate to a term of years and as much longer as oil or gas should be found in paying quantities, and stipulating for penalty in case of delay in drilling, and further providing for the delivery into pipe lines for a certain share for the guarantor of all the oil produced, and for the payment of a yearly rental for each gas well, was held not to pass the title to oil and gas in place; and was in legal effect only a mining lease and that the title to the oil and gas in place remained in the grantor.

Toothman v. Courtney, (W. Va.) 58 Southeastern, 915, Oct., '07.

Under the statute an adverse action must be commenced within 30 days after the filing of the adverse claim; and such time is determined by the statute providing that a civil action shall be commenced by the filing of the complaint and the issuance of a summons, etc.

Harris v. Helena Min. Co., (Nev.) 92 Pac. 1, Oct. '07.

A government mineral surveyor, appointed under the United States Statutes, Section 2334, was not an officer, clerk, or employee in the General Land Office, within the meaning of Section 452 of the United States Statutes prohibiting certain persons from obtaining title to government land; therefore such government mineral surveyor was not disqualified from locating a mining claim under Section 2207 of the United States Statutes.

Hand v. Cook, (Nev.) 92 Pac. 3, Oct. '07.

Richardson Automatic Weighing Machine.

While the ore is carefully sampled in the mine, the tonnage estimated, and the value of the ore in the stopes carefully calculated, and while the ore, concentrate, and tailing are accurately sampled and then carefully assayed, the weighing of the ore, which is equally as important as these other steps in ore treatment, is left to pure guess; at least such is the case at most mines and mills. The amount of ore mined is generally calculated from the average weight

of a car of ore and the number of cars pegged by some surface man. Each of these factors is liable to error, for the number of cars may be pegged incorrectly, and the average weight of the carload varies from day to day.

The weight of a carload varies owing to two quite different causes, one is natural, the other human. The amount of ore, coming from different stopes, is apt to change each shift. The weight of the loaded cars from each stope differs because the ore itself weighs more in some stopes than in others, and also because in one stope more waste rock gets mixed with the ore than in another. Both of these factors affect the weight, but their effect is insignificant compared to the human cause of variation. Not only does the weight of the load vary with the different trammers, who load it, and even with the difficulty of loading at different chutes, but it varies with the time of day, for instance, whether the car is loaded on day-shift or on night-shift. Even on day-shift the weight varies with the hour. The trammer underground knows when the foreman or superintendent is liable to be about the mouth of the shaft, and they know almost immediately when the foreman comes underground to go through the stopes. A car three-quarters loaded runs easier than a full one, and it makes a much bigger showing for the 'mucker,' who is shoveling into the chute: the partly filled car counts as much as a loaded one on the tally-board. So it is safe to say that carloads vary even with the hour of the day. Then when night comes and only the shift-boss is in charge—he, who is trying to get out more 'dirt' than the boss on the other shift—do you think the trammers are over careful to fill the cars?

So one sees that at most mines the whole basis on which the calculation of the tonnage mined depends, is uncertain. Yet from such data the percentage of extraction is calculated and compared with the theoretic percentage obtained from the assays. It does seem that the amount of ore broken,

or that treated at a mill, is worthy of more accurate determination. If it is worth while to check the theoretic percentage of extraction (and it surely is), then it is worthy the expense of checking it and not half-checking it. Gradually mining men are beginning to realize this fact. Many of the mines of the Rand are equipped with automatic weighing devices, several have been installed at mines throughout Europe; some are in use at coal mines in the United States, and a few have been installed at the metal mines.

Among the simplest of these devices is the Richardson automatic weighing machine, manufactured by the Richardson Scale Co., of New York. Richardson automatic weighing machines have been in use for several years in flour mills, cotton-seed manufactories, grain-elevators, sugar-refineries, etc.; but now their devices have been adapted to the work of weighing coal, ore, and concentrate, in short, any fragmental material. All their devices weigh by a system of equal beams, the same principle as is used in assay-balances and all accurate weighing devices. Three of their machines are especially adapted to the work about mines, mills, and smelters.

Their automatic tracks scales are automatic. No movement of a hand-lever or a hand-wheel is necessary to start the operation. The whole device is enclosed in a locked casing so that it cannot be tampered with. Only two seconds is required for a weighing having an accuracy within two pounds. This machine either registers automatically the weight of each loaded car or it adds up the weight continuously.

The automatic conveyor scale, made by the same firm, automatically weighs ore or coal transported either in a bucket or a belt-conveyor. This scale weighs each section (of an arranged length) of the conveyor passing past it and no breaking or cutting of the conveyor is necessary, as is the case when the conveyor dumps into a weighing-hopper.

The Richardson automatic ore scale is in operation at the Daly West mine, at Park City, Utah, where it has been used several years. This scale weighs an average of 400 tons of ore every 24 hours. It has given entire satisfaction to the management. By means of the automatic register

the exact quantity of ore that has passed through the machine can be seen at a glance. This scale is of the hopper-weighing type but the principle of equal-arm balancing is incorporated into its design. The ore from an elevator or from a bin dumps into a receiving hopper equipped with a reciprocating plunger which feeds the ore into the weighing hopper. The weight of the ore in the hopper, by means of a system of levers, gradually closes two gates until a final dribble balances the beam; then the hopper dumps only to repeat the process. Any clogging of the scales is prevented by the plunger feeder. This scale is especially adapted to weighing in mills and smelters; it is generally placed just below the crushers. These scales can

also be used to weigh the coal fed to the boilers either by hand-stoking or by automatic stokers. All these devices are more fully described in the interesting catalogue recently issued by the company. This catalogue will be gladly sent to interested people by the Richardson Scale Co., 5 Park Row, New York.

Pipe-Threading Machines.

Prominent among the makers of pipe-threading and cutting-off machines, is the Merrell Manufacturing Co. of Toledo, Ohio. Two types of machines made by this firm are shown in the accompanying illustrations. The first represents the portable hand machines, No. 5, 6, 9, and 11. The power is applied either by crank or ratchet lever to the shaft of the pinion, which engages the geared wheel enclosing the

dies. As the gears and bearing parts of the machine are housed, the difficulties due to dust and chips are obviated. All machines have a rapidly adjustable die-head and cutting-off knife; the chasers are set by graduation to any size desired, and may be released from threading while in motion, opened to allow the pipe to be cut, and closed instantly, one set being used to thread several sizes of pipe. The chasers can be sharpened by grinding. It is claimed for these machines that they do better

and more rapid work both in threading and cutting than any other hand machine on the market, and that they have a greater range of work and permit of quicker changes in size of pipe. The second illustration shows the hand and power machines No. 5 $\frac{1}{2}$, 6 $\frac{1}{2}$, 9 $\frac{1}{2}$, and 11 $\frac{1}{2}$. These machines are the portable hand machines mounted on a base and driven with compound gears with a cone-pulley, being so arranged that either hand or power can be used, while it is possible to take the machine from the base and use it as a portable hand machine. These two types are described at length in Bulletins No. 18, 19, and 20, issued by the company. These machines are sold and carried in stock by the Pacific Hardware & Steel Co. of San Francisco.

GRADUATES of the MICHIGAN COLLEGE OF MINES held a reunion at Houghton on Thanksgiving day. Twenty out of the 33 graduates on the Mesaba range attended and the affair was most successful. A. F. Benson was toastmaster and the following responded to toasts: D. C. Peacock, 'Possibilities'; C. K. Quinn, 'Michigan College of Mines'; I. J. Shields, 'Mining in Peru'; W. R. Van Slyke, 'Precision'; J. W. Van Evera, 'Recognition of Thanksgiving'; V. H. Rakowsky, 'A Higher Plane for the Mining Engineer.'

Commercial Paragraphs.

THE COMPRESSED AIR MACHINERY Co. reports the sale of a Word Brothers drillmaker and sharpener this week to the Pittsburg Silver Peak Gold Mining Co., at Blair, Nevada.

THE Guanajuato Consolidated Mining & Milling Co., Guanajuato, Mexico, is installing a RIDGWAY filter-press, which is said to be the first of these presses installed on this continent.

THE ECLIPSE DRILL SHARPENING MACHINE & MFG. Co., of Denver, recently sold one of their large drill-sharpening machines to the U. S. Government for use in the Gunnison tunnel at Lajane, Colorado.

ALLIS-CHALMERS Co. has engaged for its office in St. Louis, Mo., a new suite of offices, 1,302-1,304 Third National Bank Bldg., where F. L. Bunton, the district manager for the company, and the salesmen of his staff, will be prepared to receive visitors after January 1, 1908.

L. S. PIERCE, 1650 Champa St., Denver, Colo., patentee and manufacturer of the Pierce amalgamator, reports the following sales: Black Bear Mining Co., Telluride, Colo., four 20-ton machines; Smuggler Union Mining Co., Telluride, Colo., three 20-ton machines; Round Mountain Reduction Co., Nevada, one 50-ton; New York & Promotion M. Co., Quartzburg, Arizona, three 5-ton; through Fairbanks, Morse & Co., three 25-ton extra length machines for shipment to the Jenny Gold M. Co., Gold Spring, Utah. The Smuggler Union Co. already has 13 of these machines in use in their mill, which have been giving excellent satisfaction. These machines either take the place of plates or are used below plates. In a number of mills they have been installed after completing the mill and are then placed below the plates.

Books Received.

'Plane Surveying,' by John Clayton Tracy, Assistant Professor of Structural Engineering, Yale University. First Edition, 1907: John Wiley & Sons, New York; 16 mo. XXVII and 792 pp.; morocco, price \$3. This, the latest book on the subject, is a text-book and pocket-manual combined. It combines many of the admirable points of 'Johnson's Theory and Practice of Surveying' with others from Pence & Ketcham's 'Manual of Surveying'; in addition it contains much first-hand information. It is a book for beginners whether in college or in practice. Field work is treated in 360 pages; office work, 176 pages; care and adjustment of instruments, 82 pages. It gives a systematic treatment of note-keeping and finishing maps.

Catalogues Received.

THE WESTINGHOUSE MACHINE Co. of Pittsburg has issued 'Catalogue P,' describing and illustrating the Storage Batteries made by it for portable service.

THE TRAYLOR ENGINEERING Co. of New York now has ready for distribution a new catalogue entitled 'The Traylor Concentrating Table.' This catalogue not only describes the recent improvements in the construction of that table but it also describes less completely other milling machinery and some smelting furnaces, manufactured by that company.

Publications Received.

Bulletin No. 314, 'Report on Progress of Investigations of Mineral Resources of Alaska in 1906,' by Alfred H. Brooks and others, has been sent to us by the United States Geological Survey.

Dividend.

On December 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 123 of \$90,000. This makes the amount of dividends paid this year \$1,950,000, and the total to date \$9,816,000.

MINING AND SCIENTIFIC PRESS

Editorial.

RECUPERATION from the effects of speculative excesses is likely to be rapid, for the resources of the United States give it a resilient strength astonishing to the old world of Europe. For instance, the total value of the farm crops for 1907 is estimated at \$3,404,000,000, or an increase of \$478,000,000 over 1906. The valuation is helped by the failure of crops in foreign lands and the consequent high prices of cereals. A little matter of \$478,000,000 is an excellent tonic for financial debility.

IN REGARD to assessment work on mining claims, we note that the Senate has passed the bill suspending the necessity for such work for the year 1907, and it is likely that the bill will be made law in time to serve its purpose. That purpose we believe to be a mistaken one and in the interest of companies owning unpatented claims rather than in the interest of our friend the prospector, whose credit is still as good as it was before the recent financial unpleasantness.

THE BAD SEASON of the Manhattan Opera House at New York, and the passing of the De Beers dividend at London, are signs of the troublous financial times. Opera and diamonds are not necessities, and the rich forego both when incomes decrease. In regard to De Beers we remember that Cecil Rhodes, about five years ago, when presiding at the annual meeting of the diamond mines consolidation, said that they could make diamonds as cheap as glass by over-production, but as long as women were vain and men were foolish, the dividends would be forthcoming. Vanity and foolishness have not passed from off the earth, but a rival diamond company—the Premier, at Pretoria—spoil the business of the Kimberley mines, and has caused the dividend to be passed, despite an adjustment of the monopoly.

OUR DENVER correspondent refers to the fact that the mining community of Summit county, Colorado, is urging the preparation of a report on the local geology and that the United States Geological Survey is being importuned to do this work. We are glad to second this suggestion, for the investigation of the geology of the district around Breckenridge is likely to prove useful in a wide sense. To many people Breckenridge is celebrated for the beautiful specimens of native gold that have been on exhibit at national expositions. To geologists it is known that Farncomb hill, whence come these specimens, affords an interesting example of vein structure, for the ore occurs in Cretaceous shale where penetrated by eruptives belonging to the same period as the quartz felsite of Leadville. But the district has many other forms of ore deposit, besides the gold-bearing

placers that led to the first mining forty-six years ago. No part of the Rocky Mountains affords better opportunity for the study of economic geology and we hope the Director of the Survey will be able to arrange for a scientific investigation.

FATALITIES involving the loss of hundreds of lives, have occurred in rapid succession at three coal mines. Whether they were wholly unavoidable or due to carelessness, no one can say until a thorough investigation has been made. We publish a letter from Mr. S. H. Brockunier concerning the explosion at the Fairmont mine in West Virginia and his letter emphasizes the perfunctory character of the inspection made by State officials; in fact, it reminds us a good deal of the bank commissioners in California, who are incompetents appointed by the Governor as a reward for political services of a disreputable kind. When these accidents in mines take place, it is pitiful to find that they are due too often to criminal carelessness such as ought to lead to the arrest of both the inspectors and the managers. The facts are obscured by the heroism of the rescuers and public sentiment is placated by being informed that the victims are not Americans, but Russians or Austrians, just as if the sunlight were not as sweet to one as to the other. We are reminded of the news item announcing the loss of the *Mary Lane* off the coast of Massachusetts, it being stated in the despatches that 14 souls and two Chinamen were lost! Is it provincialism or inhumanity that causes people to make such queer distinctions between the relative values of human life?

AMONG the beneficent activities of the Federal Government, that of the Forest Service is notable. We take pleasure in publishing an article by Mr. John W. Nelson, of that department, on the experiments to determine how best to prolong the life of mine timbers. It is noteworthy that our correspondent at Johannesburg refers to the recognition of afforestation, or planting of trees, as important to the future of mining in South Africa. America is better blessed with forests, but the tremendous destruction of them threatens the country with a serious loss in the near future, unless steps are taken to remedy the deforestation. To the public spirit and intelligent energy of Mr. Gifford Pinchot, as Forester, is due much of the credit for the valuable work now being done by the Forest Service of the United States, both in educating people to national thrift in this regard and to actual protective measures calculated to prevent indiscriminate cutting of trees and forest fires.

THE PUBLICITY MANAGER for an important machinery house states in a circular that the striking of two veins of rich ore occurred subsequent to the placing of an order with his firm for a mill. Moral: Order a mill, and a mine shall be forthcoming by the time you are ready for it. Joking apart, such things have been done and miracles have happened. Moreover, there still lingers the idea, among people of a certain kind, that if you buy machinery from particular machinery

houses, you will get dividends from your mine. A facetious agent once promised that every mine using his pulverizer would prove a bonanza. In the old days directors from New York and London would call on Mr. William Chalmers at Chicago and order a 40-stamp mill complete, engines and vanners included, much as they would go to a trusty head waiter and tell him to set up a nice luncheon for two. Sometimes it might be added that the mill was to be "just like the one built" for the Homestake or the Montana company, the idea being that the equipment that suited a real bonanza would be right for a supposititious treasury of wealth in course of development. Those days are gone. There are more makers of machinery and better machinery, there is more care in selecting the right equipment and the result is a closer adaptation of the machinery to the ore it is intended to treat. Sensible investors or speculators take advice as to the manner of reduction suited to the ore produced at their mines, and mills are ordered not like a box of cigars or a French dinner, but upon the cautious investigation of consulting metallurgists, who get the different parts from the different firms that make specially manufactured articles. Occasionally the ore is expected to suit the mill and the caprice of the mine-owner, but nature proves refractory and money is exchanged for experience, the latter being less readily convertible into currency and therefore, in times like these, less desirable.

A Question of Policy.

TO stop development or not, that is the question. By reason of the low prices of copper and lead, it is for directors and managers to decide whether on the one hand they shall stop development and thereby minimize expenses while extracting ore in reserve so as to maintain good profits or, on the other hand, continue development, diminishing production meanwhile, so as to conserve the ore for the time when the metal market improves. Two extremes of policy are illustrated by Lake Superior and Butte. At the copper mines of the Lake country the operations are maintained steadily, regardless of the vagaries of the metal markets. Development and extraction proceed at their usual ratio no matter whether Secretan, the Amalgamated, or the United Metals Selling Co. is trying to set aside the laws of supply and demand. At Butte, on the contrary, sweeping reductions in the scale of operations, the closing down of big mines, and the cessation of smelting operations are ordered, in the expectation, apparently, of restoring the metal market to a healthy condition. Changes in the policy of the copper mining companies are made in a lordly way, highly disconcerting to local industry. It seems to us that two obligations are involved, one to the shareholders, that is, the owners of the mine; the other, to the local community. The first requires that the maximum profit be made. Is it made by violent changes of policy? The manager of a big mine gradually gathers a number of efficient employees and develops a system based upon the usefulness of such a body of men. They

settle in the locality and can be depended upon to do certain work in a certain way. It may be that exploratory work is done under contract, at so much per foot, and in dull times like these the cost is minimized owing to keen competition. If the mine is closed down pending a revival of metal prices, the force at the mine becomes disintegrated, many of the men leave the locality, and in the interval the mine itself suffers, for all experienced men know that idle workings will cave and the timber in abandoned levels will rot to such an extent as to make repairs excessively expensive when finally they become requisite on a general resumption of operations. If the mine is not closed down, but extraction ceases, while development proceeds, the shareholders get no dividends; while if extraction proceeds, while development is stopped, the shareholders get a temporary profit at the expense of destroying the future earning power of their property. But another factor comes into play, namely, the moral obligation to the community. The people of a mining community do not share directly in the prosperity of a mine, save in so far as they get the chance to work, and it is by their work, especially if it be efficient, that the company has prospered. It owes something in return and it will find its interests best conserved by having some regard for this social obligation. A director is in a dilemma nowadays and the situation is not without humor. A feverish metal selling agency pulls one leg and a working miner the other; whose pull is strongest?

A New Alchemy.

A PROFESSIONAL FRIEND sends us a letter from a promoter offering stock in a new process that is to do strange things. Processes that extract more gold than the common fire-assay have often served as a lure to people that want more than they pay for. There was Beam of lamented memory; there was Stephen H. Emmens whom Richard P. Rothwell controverted, and there have been alchemists of a later day—some deluded, others deluding. The higher chemistry has been invoked, the mysteries of radium have been quoted, and names celebrated in science have been used to beguile speculators (they call themselves 'investors') who have read turbid accounts of missing elements and fractional precipitation in non-technical and wholly irresponsible newspapers. The present story is that of a Denver Faust who has discovered a process, shares in which are purchasable with United States currency. The patent "was not issued until the process had been tested at Washington, and the Government officials saw that it would do the work." This statement puts the stamp of imposture on the affair at once, for Uncle Sam is too busy to test processes and there are no Government officials whose business it is to check the process-monger. It is easy to obtain a patent and even the comparative idiocy (from a metallurgical standpoint) of his claim will not bar issuance of exclusive rights to an inventor. According to the letter shown to us, "the discoverer was a colored man, and a practical miner. He was a self-made metallurgist of amateur ability." We expect to find 'the nigger in

the woodpile' and we are ready for statements even more highly colored than the inventor, but we do demur to "amateur ability." "In his investigation he fell onto the solutions of chemicals that would do certain work and his fellow miners sustained him while making his experiments." We trust the promoter will fall into the solution and that it will be "something with boiling oil in it." Although the other miners sustained the inventor (we hope, with pork and beans), they refused to elect him president of the company because it was found "difficult to interest capital while a negro was at the head of the corporation." Thereupon they engaged the gentlemanly financier aforesaid, who wrote the letter "to sell stock on a commission of 65 cents per share." Experiments were made with success until the directors quarreled among themselves. At this juncture "the smelter trust told the mine-owners that they must not sell their ores to the new process company, because it was in violation of contracts." So the bold bad Trust spoiled the hard work of the colored Alchemist and in consequence the patent was sold to the Promoter to satisfy a judgment obtained against the Company. He made "repeated tests" and satisfied himself that he had "the biggest money-making proposition in the West today." Seeing that he could turn \$10 ore into \$20 ore, he undoubtedly did have a "money-making proposition." But did he hug it to himself, buy a cellar, and proceed to make Rockefeller look like a rose of yesterday. No, Sir. He was an altruist; he offered a share in his epoch-making money-making coin-manufacturing enterprise to you and to me, and to all who had the price in their jeans. Then follows an account of the process; it is what the old lady called the "delirious trimmings" of metallurgy. "Ore is crushed to 120 mesh; mesh is placed in a tank; then it is covered with a solution of water, plain salt, ammonia, sulphate of iron, and then agitated. The metals that were already developed by nature fall back into the mesh from the solution. The metals that were in process of formation by nature (but which had not matured naturally until matured by the presence of chemicals among them) come to the surface in a scummy form" and so forth. Evidently the 'mesh' is a weird sort of thing, but not half as bad as getting into the toils of such a faker. He proceeds to state that ore that gave \$29 by fire-assay yielded \$12 after chemical treatment, 3 oz. ore became 11 oz. stuff, 5 oz. ore was transmuted into 17 oz. ore, and so forth. He offers an opportunity to become wealthy suddenly, by the purchase of 25,000 shares for \$2,500. As a bit of salt on the tail of an unwary bird, it is added that "it is altogether probable furthermore that by the time the process is really on the market in a commercial way, there will be a demand for the entire corporation assets from either the American Smelting & Refining or the United States Smelting company." It is a sign of the times when these two companies are mentioned as possible rivals for a process that puts gold into ore instead of taking gold out. We are in the dawn of a new era. The astrology of yesterday is the astronomy of today; chemistry and alchemy are one; spoofery and finance have kissed each other. Selah.

By the Way.

In a recent issue of the New York *Evening Post* we find the following suggestive letter, written by Mr. Henry A. Wise Wood. He says:

In order to gain a correct understanding of the causes which have brought about the existing financial crisis, one must look at the situation from a sufficient distance in point of time to enable him to detect the various steps by which it has approached.

(1) For several years past there has been an ever growing stringency of money at about this season. The facts of the regularity of its occurrence, and the increasing severity of this autumnal money shortage, call for three comments: That the thin ice of finance might invariably be expected to form during crop-moving season; that its attenuity might yearly be expected to increase; and, the foregoing being so, that an autumn at last might be expected to arrive having a financial ice-film too fragile to support financial skaters, should one of them fall.

(2) Several years ago by a writer, Ida Tarbell, for the first time the public was aroused to the immense power which it is possible for the corporation to wield, and, in the case of the nation's greatest corporation, as to how that power had been and still was being used to oppress the people and evade their laws. It may be said that then, as never before, the public as a whole understood the menace of this extraordinary corporate machine which had been devised for the people's exploitation.

(3) Shortly thereafter another writer, Thomas W. Lawson, carried the Tarbell exposure still further, and revealed to a by then thoroughly awakened public the particular machinery by which it was possible for those wielding this supreme corporate power to loot at will other, smaller, corporations, and, generally, whomsoever they chose.

(4) Immediately following upon the foregoing came the insurance exposures, which confirmed the public in its belief that its aroused fears were justified. It having been discovered that so lauded a fiduciary institution as the life insurance company (for the sacredness of which so much had been claimed) could so easily be led to go wrong, a startled people began to ask if their savings could be safe from the hands of the predatory manipulator in the till of any corporation.

(5) Next in order came the Chicago & Alton revelations; when, with another gasp, the people, still more firmly gripping their purses, began to question the safety of their railway investments in particular.

(6) By now the foregoing incidents had begun to tell upon the popular temper; how often and thoroughly the interests of stockholders had been disregarded or deliberately sacrificed for the personal benefits of those in control of their properties had at last been made clear, and the general confidence in corporate management began to totter.

The outburst of active national resentment which followed, and its resulting widespread campaigns of retaliation, are occurrences too recent to require more than passing notice. But these still further increased the anxiety of those holding corporation stocks (particularly stocks of the railroads), and a further shrinkage of values followed. The shareholder, seeing, on the one hand, the spectre of corrupt management stalking among the corporations whose stocks he held, and, on the other, that of an aroused people bent upon scotching the first spectre, and thinking himself to be between the two, very naturally wished to escape.

(7) Into the midst of this state of affairs came the

\$29,000,000 bomb of the law, and burst; when suddenly it was perceived that corporations could be held to account for their sins, *in dollars!*

This seems to have been the first time in American finance that it was borne in upon the popular consciousness that laws which conflict with moneyed interest have a standing in court, and must be obeyed, and that there may be enforced, as penalty for the wrongful acquisition of money, the surrender of money in large enough sums to be painful. The resulting consternation and flight to cover of holders of shares in involved corporations or of corporations under suspicion are perhaps the highest tribute we have ever paid to the efficacy of law for the discouragement of wrongdoing, when it is drastically enforced.

(8) Now came the exposure of the Metropolitan traction looting episode, to pull drum-tight the tension of an already over-wrought community.

(9) The confidence of the people in the integrity of the management of its corporate enterprises had at last been so successfully shaken as to have become substantially destroyed. Among those charged with corporate management the fear of retaliatory action by the people and the courts had grown to panicky proportions. Neither trusted the other, and, with mutual confidence rapidly vanishing, enterprises which had been reared in fatuous disregard of the trend of affairs, upon the presumption that previous values were normal and therefore stable, began to feel their centres of gravity shifting towards the danger point. And this strained situation happened to coincide with our, this year's, now periodic and annually increasing autumnal money stringency.

Such was the critical condition of things financial when the dynamic action of a copper stock speculator suddenly threw a violent strain upon the already unstable structure of credit which the latter was too weak to resist, and it collapsed.

(10) During the first hours of wreckage there was revealed the existence, in unexpected quarters, of sinister banking practices not therefore believed to be possible. So throwing the little confidence left him to the winds, the average depositor, believing his money to be safe only in his own possession, hastily withdrew it from bank.

Recrimination is futile, because it beclouds the philosophy of the situation by preventing a dispassionate examination of such forerunning events as culminated in the present trouble; and, through obscuring the truth by obtruding the consideration of persons, where impersonal causes alone should be sought, it is bound to lead us astray in the devising and application of remedies.

If the present *débacle*, as would seem to be the case, marks the passing of our industrial life from a period of lawlessness into one which can successfully conform to adequate laws of property and conduct and thrive therein, then few should complain of the price which is being paid. But let us not pay the price in vain. Let us take care to secure ourselves, by so adjusting and enforcing our laws that a return to past conditions of lawlessness shall be simply impossible; and by so ordering our industrial activities that they shall seek, and benefit by, instead of suffer from, the rigid application of law.

According to James M. Beck, one of the underlying causes of the present financial convulsion is the dislocation of our Constitutional machinery, due to the superior forces of steam and electricity. They have caused the respective orbits of the States and Federal Government to overlap, with the result that today we are attempting the impossible governmental problem of having, as to commerce, two sovereignties supreme in practically the same orbit.

Personal.

HIRAM W. HIXON is now residing at Philadelphia.
HENRY W. CATLIN has recently been to Oaxaca, Mexico.
FRED. A. GOWING, recently at Cananea, is in San Francisco.

OSCAR B. PERRY has returned to New York from the Yukon.

DONALD F. CAMPELL will spend Christmas in San Francisco.

HERBERT W. ROSS leaves for Cerro de Pasco, Peru, on December 28.

H. DEC. RICHARDS has returned to Orleans Bar, in Siskiyou county.

PERCY WILLIAMS has returned to Los Angeles from Fairview, Nevada.

SCOTT TURNER is expected in San Francisco next week from Nevada.

J. V. N. DORR has returned to Denver from the Black Hills, South Dakota.

J. H. MACKENZIE came from Goldfield to spend Christmas in San Francisco.

W. N. CUMMINGS is with the Southwestern Mines Syndicate, at Tucson, Arizona.

W. H. WASHBURN, recently in Alaska, is now at Millispaugh, in Inyo county, California.

J. M. PABKER is surveyor and mine sampler at the Abangarez gold mine in Costa Rica.

G. B. KITTO is assistant to the smelter superintendent of the Tye Copper Co., of Ladysmith, B. C.

W. H. KNOWLES, formerly at Idaho Springs, is general manager for the Pacific Mines Option Co., at Los Angeles.

HENRY LOCKHART, JR., of the Consolidated Metals Co. of Mexico City, is now at New York, with L. Vogelstein & Co.

W. B. FISHER has resigned as assistant to the superintendent of the Federal Mining & Smelting Co., at Wallace, Idaho.

WM. WELLS ELMER is general manager for the Hinds Consolidated Mining Company operations at Santa Barbara, Mexico.

E. A. BEHR, formerly of L. Vogelstein & Co. of New York City, is now with the American Smelting & Refining Co. at 71 Broadway.

M. L. SUMMERS, a gold-dredge operative with the Canadian-Klondike Mining Co., Dawson, Alaska, is at San Jose for the winter.

A. D. MOFFAT has resigned as superintendent of the Cactus mine of the Newhouse Mines & Smelters Co. in Beaver county, Utah.

JOSEPH MACDONALD passed through San Francisco on his way from Guanajuato (Mexico) to his home at Portland, Oregon, where he will spend the Christmas holidays.

FELIX CREMER, formerly with the Guanajuato Amalgamated Gold Mines Co., at La Luz, has accepted a position as ore-buyer with the Cia. Metalurgica y Refinadora del Pacifico.

J. V. RICHARDS is at St. Luke's Hospital, Denver. He was hit on the head by a piece of rock as big as a football, knocked off a ladder, fell 65 ft. vertically, and is not seriously crippled, at least he writes saying that he is coming out of the hospital "as good as new."

L. VOGELSTEIN & Co., of New York, give the following figures concerning the German consumption of foreign copper for the period from January to October, 1907:

Imports of copper.....	103,865 tons
Exports " "	7,470 "
Consumption.....	96,395 tons

as against a consumption during the same period in 1906 of 101,715 tons. Of this quantity 82,351 tons were imported from the United States.

General Mining News.

ALASKA.

The Nome Mining Co. of Nome intends to begin about the middle of next June to operate a dredge of a capacity of 5000 cu. yd. per day; it was designed by E. S. Smith and the buckets, etc., were supplied by the Taylor Iron & Steel Co. It is the largest dredge in that section of Alaska and the company does not anticipate any serious difficulty because of frozen ground.—It is reported that there has been a scarcity of medium-skilled labor in Nome and vicinity during the past season; this may in part account for the fact that the output from this section during 1907 will probably be \$1,250,000 less than during 1906. A very large increase is anticipated for next year.

ARIZONA.

COCHISE COUNTY.

At the Calumet & Arizona mines the plan has been to carry on important development work instead of producing a large quantity of ore. New orebodies first exposed a few weeks ago on the 950 and 1050-ft. levels have been found to be very large. Since the beginning of the depression in the copper market, the company has opened up practically new ground with most favorable results; this is true both at the Irish Mag and Oliver mines. When the price of the metal improves it is expected that shipments to the smelters from both shafts will far exceed those of former times.—The smelter output for November of the Copper Queen company showed a decrease owing to the plan of development work pursued and to the preparation for a new system of taking the ore from the stopes to the railroad. Good progress has been made in sinking the Sacramento shaft; the upper levels are being driven to connect with those being run from the Gardiner, Lowell, and Holbrook. A contract has been awarded for new electric pumps which will be of smaller capacity than the variety now in use. The construction of the new power house is progressing rapidly.—On the lower levels of the Superior & Pittsburg mine orebodies of large dimensions are being developed. All of the November working force has been retained; shipments to the smelters held up pretty well and were principally from the Hoatson, Cole, and Junction shafts.—At the Denn-Arizona mine, the boring of a diamond-drill hole from the 1100-ft. level was begun.—The mill at the Le Vanita mine has been running on ore carrying lead and gold. The lowest workings of the mine are down 225 ft. in a fissure vein in granite and the best ore is found at that depth.

GILA COUNTY.

The new electric hoist in the 200-ft. winze of the Old Dominion mine has been installed between the 14th and 16th levels and it is expected that the work of developing the latter level will progress rapidly.—The Payson Gold M. & M. Co. has shipped machinery from Mesa via Roosevelt for the erection of a mill at its mine.—The Saddle Mountain Mining Co. has filed a mortgage for a large sum on its property at Christmas; it includes the mine and smelting plant. It was made for the purpose of discharging the company's indebtedness and to create an operating fund to be used when the copper market shall have returned to normal conditions.

GRAHAM COUNTY.

The Gold Belt Development & Reduction Co. shipped two cars of high-grade copper ore from its mine at Morenci to the Shannon smelter for treatment. The same company has begun shipping from its gold claims and has nearly a carload in the railroad yard. The ore carries well in gold besides considerable value in other metals. This is the first gold shipment made by this company and the result will be watched with much interest.—The Shannon Copper Co. at Clifton is having a concentration test of its ore made at Concentrator No. 6 of the Arizona Copper Co. at Morenci.—Bids have been called for by the Home Copper Co. for the drilling of a 1000-ft., a 2000-ft., and two 500-ft. holes on its property. The bids are to be made in two forms; fur-

nishing the drill and full equipment, and on the work alone with everything furnished.

The Bacon & Langerman silver mine, east of Morenci, is under development and occasional shipments of ore are being made to the smelters.—At the Chase Creek mine, driving an adit to develop a large body of low-grade ore continues.—Louis Ferber and associates are making occasional carload shipments of gold-silver ore from the Morenci district to the Douglas smelters.—At the Standard copper mine, the force on development work has been curtailed, but regular shipments of ore are being made to the D. C. smelter at Morenci.

MOHAVE COUNTY.

The Victor Gold Mining Co. is building a large mill and cyanide plant at its mine near Vivian.—Sinking is in progress in the P X mine in I X L basin; large bodies of lead-silver ore had been opened to water-level, but the ore recently found in the shaft is of better grade.—The mill at Stockton Hill is turning out a large amount of heavy lead concentrate.—Work will be stopped in the Pyramid mine on account of the installation of heavier machinery; this will be operated electrically.

PINAL COUNTY.

A mining excitement has been caused in the neighborhood of Mammoth by the discovery there of gold-bearing ore.—E. R. Stafford has shipped a carload of high-grade copper ore to the El Paso smelter.—W. McGrew and J. Schwartz have recently sunk a shaft on their claims at the head of Cottonwood canyon; on reaching the water-level it cut a vein carrying chalcopryite and bornite, besides some gold and silver.—Work has been suspended at the Copperosity mine until the financial situation throughout the country becomes more nearly normal.

SANTA CRUZ COUNTY.

At the Llano copper mine, near Llano station, work is progressing satisfactorily, and good orebodies are being developed.—Stephen O'Connor is developing the Joe Wheeler, Winnebago, Chief, and Ivanhoe claims near Duquesne; he has sunk 60 ft. in ore.

YAVAPAI COUNTY.

At the Fitzhugh Lee mine 25 men are employed. They are driving an adit to reach a rich ore-shoot which is exposed in a higher tunnel; they are also sinking a winze on the ore. A hoist is to be installed in the upper tunnel. The mill has been thoroughly overhauled and is ready to begin crushing several hundred tons of ore from the Bordeaux mine, which is owned by the Money Metals Mining Co. G. P. Henderson is superintendent of the Fitzhugh Lee mine.—The Silver Chord mine in the Black Canyon district has been bonded to C. W. Ruffner. A 50-ft. adit, it is said, exposes 46 in. of ore carrying \$60 per ton.—The Octave Mining Co. intends to add 40 stamps to its mill at the Octave mine; also to install a 1000-hp. electrical plant near Wickenburg on the Hassayampa river. The transmission of some of this power 14 miles to the mine will dispense with the hauling of oil. Power will also be furnished to a number of other mines in the same section; the purchase of 600 hp. has already been guaranteed. The electrical plant will cost over \$150,000 and the addition to the mill at least \$65,000. At the Octave mine 178 men are working. Some of the shafts are down about 2000 ft., the newest one, the Joker, is now 500 ft. deep. There is said to be blocked out over 180,000 tons of ore; it carries an average of \$9 gold per ton. The mill crushes 140 tons per day; a recent clean-up yielded a \$20,000 bar of gold.—The Monte Cristo mine has been bonded to the Yavapai Silver Mines Co. Jennings Bros. have been operating the property under a lease during the past year. They have made several carload shipments of high-grade silver ore; the net proceeds from this ore, which was taken out in development, has paid all operating expenses. There is a large amount of ore in sight at the mine and on the dump; some of this carries 100 oz. silver per ton. Preparations are being made to develop on a more extensive scale.—At the Bordeaux mine in the Big Bug district, the drift on the 100-ft. level has followed the ore-shoot for a distance of 150 ft., the ore

varies between one and three feet in thickness. Some of the ore from the drift is being treated in the Arizona M. & M. Co.'s mill near Poland. It is expected to yield \$10,000 worth of concentrate besides the gold caught on the plates.

The new mill of the Mt. Tritle Copper Co. in the Slate Creek district, has been completed; it is of the Nissen pattern, 30 tons daily capacity. Ore-shoots recently found in the upper and lower adits of the Mt. Tritle mine are proving better with every foot gained in these openings. The property is equipped with an air-compressor, power drills, and electric-light plant.

YUMA COUNTY.

The second payment has been made by David H. Hyman on the North Star group of mines in the Kofa district; this property is better known as the 'Mayhew strike.' A 50-hp. air-compressor has been ordered, and it is intended to erect a 20-stamp mill.—At the Ibex-Plomosa mine, work will be resumed after the holidays. As the first shaft caved at a depth of 60 ft., a new shaft will be sunk.—The Little Dutchman, Reid, and Old Maid prospects in the Bouse district have been bonded to a Michigan company.

CALIFORNIA.

CALAVERAS COUNTY.

The trouble between the operators and employees of the mines at Angels Camp, reported last week, has been adjusted; the management of the mines conceded to the men the 15 mln. claimed by them as their right.—It is reported that the Utica company will engage a large force of men in the near future.—At the Melones mine about 75 men are employed; the mill is dropping 100 stamps. A new flume has been built much higher up on the hillside than the one destroyed by a flood last spring.

ELDORADO COUNTY.

The lessees of the Blue Rock mine, in the Georgetown district, have found a gold nugget worth \$318.—It is said that the owners of the Mt. Pleasant mine are preparing to substitute electricity for the present motive power; this is to be generated at the Cosumnes river.—Nic. Ferretta and Ed. Christian are preparing to re-open the Sunnyside mine near Newtown.

INYO COUNTY.

The mines of the Ballarat district are quite active. The machinery for two new reduction plants is on the ground; one is for the Snow Canyon Mining Co. and another for a property at the south side of the district.—D. D. Johnson has secured a bond on the Neylon group of mines in the White Mountain range.—At the Dunlap mine an ore-body has been found at the end of an adit 600 ft. long.—At the Red Rose mine ore of great richness is reported.—Development continues at the Black Canyon mine.—At the Gray Butte mine the adit has been driven 100 ft. and in its face has ore 6 in. wide; this is said to assay \$80 gold per ton.—The recently built Keane Wonder mill, on the edge of Death Valley, has made its first shipment of bullion, amounting to \$16,000, the result of 12 days' run.

An adit is being driven at the Black Canyon mine to develop at depth a large lode of milling ore recently discovered near the surface.—At the True Fissure mine the main vein has been cut in the adit at a depth of 200 ft.; it is 13 ft. wide and is said to assay about \$12 per ton.—A large amount of development work has been done during the past summer at the Bishop Creek mine; in the upper workings a large tonnage of fair-grade ore has been exposed.—At the Killian mine the adit is in 300 ft.; several well defined veins carrying fair values have been found.—High-grade silver-lead ore has been opened a short distance below the surface at the Bishop-Ellis mine in Marble canyon.—The Buckeye M. & S. Co. has begun sinking a double-compartment shaft at its mine on Poverty hill; it will be 500 ft. deep.

MONO COUNTY.

At the Golden Gate mine 14 men are working. The tunnel is in 175 ft., and will be continued 700 ft. farther to the old workings. It is intended to erect next spring a 10-stamp mill beyond the snowslide zone.

NEVADA COUNTY.

The Iron Mountain copper mine has been closed for the winter.—A 10-stamp mill will be erected by the Canada Hill Consolidated Co. A. Charonnat is superintendent of the mine.—Good ore has been found in the Blue Rock mine; it is on the west rim of the old Badger Hill hydraulic gravel mine.—Work is progressing in the development of the ore-shoot recently found on the 900-ft. level of the Banner mine.—At the Boss mine development continues with encouraging results.—A number of miners who have been working 'tribute pitch' at the New York-Grass Valley mine have made a nice clean-up after operations extending over several weeks.

PLACER COUNTY.

Work has begun at the Boulder mine, at Ophir; C. Cooper is in charge.—A 2-stamp mill has been completed at the Rueblin mine.—At the Grey Eagle mine the work being done is confined to cleaning and retimbering the adit.—C. W. Kellogg is erecting a hoisting plant at the Klondike mine.—At the Hidden Treasure mine the gravel in the 'blue lead' is prospecting well. The ground has been blocked out and gangways opened so as to afford room for a large force of men to work.—The buildings have been completed and most of the machinery placed in position at the Herman mine.—Twenty men are employed at the Megeachen mine; Elmer Rose is superintendent.

PLUMAS COUNTY.

A force of engineers under H. S. Turner, representing the Forest Service, is making an examination of alleged mining lands to determine whether they are properly classed as such.—At Pilot Peak an adit is being driven by Plume Turner and brother to develop at depth a lode from the outcrop of which they secured some rich ores some time ago.—The old drift mines at Saw Pit are being reopened by George Sanborn.

SAN BERNARDINO COUNTY.

A discovery of mica of commercial quality is reported to have been made by J. D. Ball near Ivanpah. It is stated that the vein can be traced on the surface 500 ft.; the owner displayed a sample 12 in. wide, 14 in. long, and 1 in. thick; from this he split off, without cracking, a plate one-sixty-fourth of an inch thick.

SHASTA COUNTY.

The Sacramento Valley & Eastern R. R. has been finished to Heroult. The electric iron smelter at Heroult has been closed for a few days, pending the installation of new machinery. A 250-kw. transformer arrived at Redding for this purpose. Prof. Dorsey F. Lyon, of Stanford University, has been granted a six months' leave of absence for the purpose of completing certain experiments in designing a new furnace for the Heroult smelter.—The bond on the Golin-sky mine, which is held by the American Smelters Securities Co., has been extended for a period of one year. The work being done in the mine is said to be resulting encouragingly. The bonding parties will continue shipments to the Selby smelter.—The Clear Creek dredge, which is being constructed by the Consolidated Gold Dredging Co., is nearly ready to launch. It is 84 ft. long and 35 ft. wide. It will draw two feet of water.—The Garrecht mine, near Shasta, has been sold; it has been under development for two months.

The Afterthought mine was closed on Dec. 14. The smelter at Ingot will continue in operation until the ore on hand is treated.

SIERRA COUNTY.

The Sierra Buttes mine is not working its full crew on account of not being able to get enough timbers for the winter.—The Cleveland mine has resumed operations after an idleness of many years.—At the Keystone mine the mill which was destroyed by a snowslide has been replaced by a new one and other repairs are about completed.

SISKIYOU COUNTY.

Supplies have been packed to the Yellow Rose mine, preparatory to resuming work. This mine is nearly 7000 ft. above sea-level.—A long and bitter litigation over the Garvey Bar hydraulic property, on the Klamath river, 12

miles below Hornbrook, has been ended. The bar contains 80 acres of gravel of proved value; it was sold several years ago to the Klamath River Gold Mining Co. This company prospected the property; on Aug. 31, 1904, the ancient channel was found. An injunction stopped work, but later one of the original owners was placed in charge; in six weeks, working only two men, he took out \$22,000.—At the Champion mine, on Humbug creek, a contract is to be let for a 1000-ft. tunnel; air-drills and an electric lighting plant will be installed.

STANISLAUS COUNTY.

A Colorado dredging syndicate has been bonding lands along the Tuolumne river between La Grange and Modesto. It is said that samples of gravel taken from the river channel carry good value in gold.

TRINITY COUNTY.

At the Golden Jubilee mine, near Coffee creek, a new 20-stamp mill is being installed. The cyanide process is applied in treating the tailings. A drift has been extended along the vein a distance of 400 ft. on the 200-ft. level; this has developed a number of lenses of ore.—All the machinery has been removed from the old dredge that has been marooned above Trinity Center for more than a year. The owner, an Illinois corporation, is building a dredge near Callahan.—It is expected to resume operations within a short time at the Quimby mine near New river; provisions have been packed in and a force of men will be secured as soon as possible.

Forty-four miners have attached the Bonanza King mine for \$6000 due them as wages. The attachment is an outgrowth of the failure of the California Safe Deposit & Trust Co., in which the owners of the Bonanza King were largely interested as stockholders, and from which was borrowed the money to develop the mine.

TUOLUMNE COUNTY.

Workmen are grading for a 10-stamp mill at the Lion mine.—A trustee's deed of sale of the old John Royal mine, near Columbia, has been given to Albert and Charles E. Smith.—At the Omega mine sinking has been resumed in the main shaft at a depth of 350 ft.; it will be sunk 100 ft. deeper.—The Eagle Shawmut mine was to resume operations on Dec. 19 after being closed six weeks in order to give everything about the mine and mill a general overhauling.—Eighteen men are sinking the shaft at the Joy Mining Co.'s property at Jacksonville.—At the Harvard mine the mill was started on December 17, after having been idle for two weeks for want of electric power.

Good progress is being made in rehabilitating the old Brandy City hydraulic mine, above Camptonville. More than 50 men have been employed for several months in building about six miles of road from Indian valley to Brandy City, in constructing a bridge across the North Yuba river, and in rebuilding the Hoosier flume. A saw-mill is being erected on Little Canyon creek. The company will build restraining dams in accordance with plans already approved by the U. S. Debris Commission. Frank Strandburg is general foreman for the company.

COLORADO.

CLEAR CREEK COUNTY.

At the Specie Payment mine the new electric plant has been started and shipments of ore to the Newton mill were resumed on Dec. 12.—At the Shafter mine all work is being carried on through the Big Five adit since a connection was made with the Shafter shaft; the shipment of ore of smelting-grade has begun.—A trial shipment of ore from the 700-ft. level of the Lamartine mine returned \$50 per ton.—At the Quito mine there was found a streak of ore so rich in gold in a free state that panning was adopted and the gold sold at the mint.

LAKE COUNTY.

Operations have been resumed at the Walden mine, which has been idle for many years. It contains a body of first-class iron ore which is being mined and sent to the smelter.—The Emerald Mining Co. in driving an adit at its mine at Chalk ranch, is nearing the point where it expects to cut the main vein.—The Breece Hill district continues

to be extremely active, and the properties being worked are shipping a good grade of silicious, sulphide, and iron ores; a large number of men are employed. The usual tonnage is going out from the Little Johny, Fanny Rawlins, Big Four, Penn, M. N., Gold Basin, and Highland Chief mines.—A stamp-mill has been erected on the Miller group of claims in Lackawana gulch.—The Arkansas Valley smelter is operating practically all of its furnaces and consignments of ore have shown little decrease.

IDAHO.

BLAINE COUNTY.

The Five Points group of mines, a few miles north of Soldier, has been bonded to Mrs. E. C. Atwood. The property has two well-defined veins that carry gold, silver, and lead. Several thousand tons of ore are exposed in the workings down to a depth of 700 ft.—Operations were resumed on Dec. 18, with a full force of men and teams, upon the dam and ditch being made to supply water to the electric plant to be installed by the Idaho Mines Consolidated Co.—Work is soon to be resumed on the claims of the Rosetta Mining Co., in the Little Smoky district.

IDAHO COUNTY.

At the Anaconda mine, in Newsome district, work is to be resumed in a short time; it is expected that 10 to 15 men will be employed during the winter.—The Oregon Mining Co. has a large crew of men working on its Summit Flat property.—John and Earl Hokenson recently found a 5-ft. lode of ore in the Sunshine mine at Orogrande.—The Frisco Mining Co. has begun driving a new adit on its property; it will be nearly 700 ft. long. George C. Glatz is superintendent.

NEVADA.

CHURCHILL COUNTY.

The Piroutte Gold Mining Co. intends to install a 25-hp. hoist at its mine at Wonder. The shaft is now 103 ft. deep. It was started on an 18-in. vein; from ore at the depth of 85 ft. assays as high as \$167 per ton were secured.

ESMERALDA COUNTY.

On Dec. 20, Governor Sparks received a message from President Roosevelt advising him that the troops would be withdrawn from Goldfield on Dec. 30. The President's reasons for the withdrawal of troops are that there does not appear to be a state of insurrection in Goldfield, and in the absence of such condition, the United States troops would only be doing police duty while on the ground. The State Government has failed to perform its full duty and Governor Sparks seems disinclined to convene the Legislature to consider the formation of a State military force. The Goldfield Mine Operators' Association has announced that the presence or absence of the troops will not affect its position. It will employ guards and discharge, as far as possible, the duties that it feels really belong to the State and Nation. O. N. Hilton, attorney for the Western Federation of Miners, on Dec. 19 addressed a letter to the mine owners requesting a conference where the differences might be at least temporarily adjusted; but the Goldfield Mine Operators' Association replied that it would be useless to meet Mr. Hilton, as attorney for the Western Federation of Miners, as any attempt at compromise or new agreement with that body could not lead to permanent peace. Independent workers for the operation of the Goldfield mines have been arriving from outside points all week. They have been met at the depot by representatives of the mine operators and taken at once to the quarters provided at Jumbotown, in the heart of the mining district; here they were housed and fed. These men have been selected with great care, because they are expected to become permanent employees. They will be put to work principally in the Mohawk mine; the experienced shaft-men will sink the main shaft below the 450-ft. level. It is intended that by the time the troops are withdrawn, the whole district will be supplied with miners from outside points.—The Elks Consolidated lease on the Yellow Tiger claim has been worked during the strike in the Goldfield district. A three-compartment shaft has been sunk to a depth of 530 ft. At the 500-ft. point it penetrated a large vein which is reported to carry a value of \$14 per

ton.—Charles Rookard was arrested on Dec. 17 on complaint of the Little Florence management; $6\frac{1}{2}$ tons of ore valued at \$4000 were found in his possession.

HUMBOLDT COUNTY.

The recent rich strikes in Wild Rose canyon in the Seven Troughs district have greatly stimulated development work in that section. In Wild Horse canyon the returns in the pan are as good as in any other canyon in the district.—The Seven Troughs Kindergarten Co. expects to begin the construction of a 10-stamp mill about Jan. 1. It will handle custom work and will be of great benefit to lessees who have developed ore of milling value. Tests will soon be made upon the ores of the district to ascertain the cost of treatment; it is estimated that it will average \$5 or \$6 per ton. It is said that many properties in the district have large bodies of ore carrying \$8 to \$35 gold per ton.—At the Eclipse mine a lode 25 ft. wide has been cut at a distance of 125 ft. in the adit; it is said to carry \$5 to \$25 gold per ton.—At the Sunlight mine at Spring Valley a large amount of ore is being mined and shipped to the smelters.—At the Bonanza King mine only the second-grade ore is being milled, but regular shipments of bullion are being made.

LANDER COUNTY.

The Nevada Equity Mines Co. discontinued work on account of the non-arrival of necessary timbers.—At the Dudley B. mine the north drift has reached good ore three feet wide.—The lessees at the Jack Pot mine are sacking high-grade ore.—Ore shipments, it is expected, will soon be resumed at the Watt mine.—The shaft at the Wholey mine will be cleaned out and more miners will be put to work.—At the Austin mine, Leutjues & Quigley have been driving an adit on a vein averaging 8 in. wide.

LINCOLN COUNTY.

Work is in progress on the 100, 150, and 300-ft. levels of the Duplex mine at Searchlight. A new orebody has been found in the main shaft at a depth of 300 ft.—At the Parallel mine ore is being sacked to make up the first carload for shipment; it is supposed to carry \$70 gold per ton.—The owners of the Silver Legion mine intend to erect a reduction plant, but have not yet decided upon the type.—A body of ore 10-ft. wide has been cut in the Mizpah mine; it is supposed to carry an average value of \$35 gold per ton.—Free gold has been found at the bottom of a 30-ft. shaft on the Bonanza group of claims at Searchlight.—The Aftermath claim of the Empire group at Nob Hill has been leased for two years to Alexander Rannie. There is on the claim a 45-ft. shaft which exposes a lode three to five feet wide; this is said to carry \$37.50 per ton.—At the Wyoming-Searchlight mine a new orebody has been found at the 200-ft. level. It is described as a vein over two feet wide of solid quartz which will average \$25 per ton.—Work is progressing on the tunnel which is to be driven through the hill at the Epistrete mine at Eldorado Canyon.—At the Red Light mine a vein two feet wide of apparently good ore was found at the bottom of a shaft 30 ft. deep.—It is intended to begin development work at the Boulder mine about Jan. 10.—The owners of the Philadelphia-Searchlight mine are planning the erection of a mill.

NYE COUNTY.

(Special Correspondence).—At present there are about 75 men working in Manhattan, including those employed at the mines and mills, and those doing assessment work. In spite of the efforts of the local and Tonopah papers to boom the camp, it is in rather a bad way, and this winter will be a hard one here, as in many other Nevada camps. It was thought that the starting of the 10-stamp mill of the Manhattan Ore Reduction & Refining Co. would stimulate speculative interest in the camp, but the mill has run but little as yet, and is still hardly ready for operation. Three days after the stamps first started dropping, the masonry foundation under the motors gave way, a concrete retaining wall had to be built around it, and the drop of the stamps lowered from 6 to 4 in. The cyaniding department is not yet finished, and the slime is being stored in the storage tanks. Lack of any money with which to pay the men is

handicapping the completion of this plant, and at present the mill-engine is broken down, necessitating a shut-down.—The 10-stamp mill of the Nevada Ore Purchasing Co. has just started, running on lease-ore from the Union No. 9 claim. This plant differs from the other mill in that it has no tube-mill, and will treat sand and slime separately, the latter by agitation and decantation. In addition to these two mills, a small plant is being erected, in which a Huntington mill will be used for crushing.—The Manhattan Consolidated company has hauled about 40 tons of ore per day for six weeks, to the custom-mill, where it is being stocked, but the production has now been cut to 20 tons, and no ore is being hauled. This is about the only property in camp that is breaking ore at present. This ore is mined through two stope-raises that are being run from the 100-ft. level to the surface. The ore occurs in an irregular chimney between limestone and schist, and its lateral limits are pretty sharply defined. This ore has been cut at one point on the 200-ft. level, but there it is lower in grade. A good

Map of Eastern Nevada.

deal of stibnite is found with the ore, and this may cause trouble at the mill. Robert Thomas, formerly at Grand Encampment, is the superintendent.—The Thanksgiving company continues to report daily strikes. One small machine is working on the 236-ft. level, driving on the vein, which is there about a foot wide, lying between limestone and schist, and near a porphyry intrusion. It is understood that some milling ore has been found. W. H. Mott, a lumberman from Michigan, is the superintendent.—Two men are working in ore at the Wolfstone mine.—Exploration work at the Granny mine is being carried on at the 50, 100, 200, and 300-ft. levels. Three beds of limestone have been cut by the vertical shaft, and some ore has been developed in two incline shafts.—The Briggs & Evans lease-dump on the Union No. 9 will be trammed to the mill of the Nevada Ore Purchasing Co. C. R. Evans estimates that the dump contains 3400 tons of ore, that will average \$26 per ton. This was the richest lease ever operated in Manhattan.—Lessees are operating on the Buckboard, Tip Top, and Union No. 4 claims. On the latter ground, two gasoline hoists have been erected, and some ore has been opened in pockets in the limestone. All the banks but one remain closed, and money is scarce; payments to the men being made in stock, by several of the leading companies. The local electric lighting plant, which was operated at a loss for a long time, has been permanently closed down.—The placer lease on the Little Gray claim that

was operated by Cole & Burns, has been closed down for the winter. Some good dirt has been put through the sluice-boxes, and all the clean-ups have been satisfactory.—There are over 250 incorporated companies in Manhattan, and out of this number perhaps a dozen are working, with small forces.—The Pioneer Leasing Co. has pulled its pump and closed down. A little ore was encountered, but not enough to warrant further work; the company still owes its men for two months work.

Manhattan, Dec. 18.

The ore shipments from the Tonopah mines for the week ending Dec. 18 amounted to 5002 tons. The Tonopah Mining Co. sent to Miller 1952 tons, to the Western Ore Purchasing Co. 535 tons, and to Virginia City 699 tons; the Belmont mine sent 1418 tons to Miller; the Extension mine sent 169 tons to Garfield, Utah; the Midway sent 195 tons to Charles Butters at Virginia City; and the Montana-Tonopah sent 34 tons to Vallejo Junction.

NEW MEXICO.

The Anderson-Apache company's mines near Hachita will be worked by contract. William J. Williams of Silver City has been given the contract.—The Copper Gulf Development Co. is endeavoring to increase its holdings in the Burro Mountain district to about 1000 acres. It is said to have 100,000 tons of ore developed by the 200-ft. level of the Virginia mine. This ore is a sulphide which carries between 2 and 4% copper. Other mines in the district are characterized by a barren zone which varies in depth from 100 to 200 ft., beneath this are large bodies of low-grade copper sulphide ore.

WASHINGTON.

SNOHOMISH COUNTY.

Eighteen sacks of rich ore were brought to Tacoma by Robert Fife and a miner. They were offered for sale at the Tacoma smelter, but refused because the ore resembled that found at Goldfield, Nev. This ore, as indicated by a test at the smelter, may contain \$8 gold per pound. It now appears that it came from a vein discovered in October near Bear Gap in the Cascade mountains; the vein is said to be four or five inches wide.—The Bonanza Queen mine at Silverton is again in operation.—A new stamp-mill has been erected at the Hidden Treasure mine near Twisp.—A rich silver vein, it is reported, has been discovered on Martins creek in the Silverton district; some development work has been done on it this season.—A clean-up of the cyanide plant at the Bonita mine is said to have yielded 45 lb. of gold.—The Hellan Mining Syndicate is completing its mill in the Swauk district.—The Gallaher M. & M. Co. is shipping concentrate to the Tacoma smelter; this company's equipment consists of a stamp-mill and a Card concentrator.—The Washington quicksilver mine in the Cle Elum district will be operated all winter; retorts for refining the product have been reconstructed.—Two carloads of concentrate were shipped recently from the Wayside mine at Granite Falls. After the arrival of a new air-compressor it is expected to ship two or three carloads per week. Forty men are employed in the mine and ten in the mill. The mining is done on five levels reached through a shaft 500 ft. deep. The ore concentrates about one to ten, and the value of the concentrate varies from \$60 to \$80 per ton.

CANADA.

BRITISH COLUMBIA.

It is understood to be the intention of the Yale Mining Co., which operates the Nickel Plate mine at Hedley, to return to the scale of wages which was in force some months ago; this scale is about 50c. per day less than the present wage scale. The company has given the men 30 days' notice of the reduction.—Supplies sufficient for the winter have been taken to the Independence mine in the Bear creek district. Five men will be employed. This mine produces a low-grade copper ore.—A carload of ore has been sacked at the Carney mine but will not be shipped until the market is more favorable.—At the Snowshoe mine eight men are employed.—No work is being done at the Mother Lode mine except the installation of some machinery.—Slater & Johns, who have a bond on the

Riverside mine, have made a 20-ton shipment to the Trall smelter.—The work of building a steel flue dust-chamber at the Granby smelter, and of extensive additions to the coke and ore-bins is going steadily along under contract. There is now a more confident feeling that the management of the Granby company and the unions will agree on a wage scale and that both mine and smelter will be in operation in a short time.—At the Aurora mine satisfactory progress is being made in opening up a good body of ore.—While sinking a shaft at the Maggie mine near Cody, a new lode containing 24 in. of clean galena was uncovered.—The Canadian Concentrating & Smelting Co. has closed a contract to ship 1000 tons of ore monthly to a concentrating plant at Toronto.

The output of the Rossland mines for the week ending Dec. 14 was as follows: Centre Star, 4235 tons; Le Roi, 2555; Le Roi No. 2, 630; total, 7420 tons.—The ore received at the Trall smelter for the week ending Dec. 14 was from the following mines: Centre Star, 4347 tons; Evening Star, 30; St. Eugene, 574; Josie, 669; Standard, 23; North Star, 96; Rambler-Cariboo, 63; Ruth, 66; Whitewater Deep, 23; Elkhorn, 16; La Plata, 24; Vancouver, 21; Duncan, 19; total, 5971 tons. There has just been completed a shipment

Map of Part of British Columbia.

of 250,000 oz. of silver from the Trail smelter to the new Canadian mint.

Arrangements have been made at the Nelson custom-house for the shipment of 900 tons of zinc ore from the Vancouver mine in the Slocan district, to Antwerp.—At the Monarch mine at Field, a new body of rich silver-lead ore has been found in driving a cross-cut from the end of the main adit.

YUKON.

The Yukon Gold Co. employs the largest winter force ever known in the Klondike under one management. One large dredge is completed at Ninety Below on Bonanza creek. Three others are building on Bonanza creek and others on Hunker creek; they will be operated by electricity. Three large electric conveyors are being installed on Bonanza creek. A hundred teams are hauling 3,000 tons of pipe-line material from Twelve Mile Landing, on the Yukon river. A great dam is being built on Bonanza creek to supply water for electric lifts and conveyors; and a power ditch at Twelve Mile will generate electricity to operate the dredges and other equipment.

Much development work has been done during the past season on the property of the Arctic Cliff Copper Mining Co. in the White Horse district; it is said that there are now blocked out 100,000 tons of ore that carries about 5 or 7% copper and \$4 or \$5 in gold and silver per ton.

Special Correspondence.

Johannesburg, Transvaal.

Working Costs.—Loss of Chinese.—Reduction of Working Hours.—Planting Trees for Ties.—October Results.—High Stamp Duty.

Most frantic efforts are being made on the Rand to reduce working costs on the mines. During the last six months there has been distinct decrease in working costs. Almost every mine shows a reduction. The principal saving is in white wages, for since the strike the white men have done more work for less pay. The working costs on the Robinson mine six months or so ago were well over 20s. per ton. Last month they worked for 14s. 9d. per ton, and as this mine has every facility for cheap working, such as wide lodes, large stamping capacity, etc., the figure should be maintained without much trouble.

The vital question is: "Can these reduced working costs be generally maintained?" Every effort is being made to keep down expenses. Wholesale retrenchment both at the head office and on the mine is the order of the day. In many cases one man is doing the work formerly done by two. As far as white labor is concerned, the reduction in costs will be maintained. But with colored labor it is quite different. Much of the reduction of costs is due to the high efficiency attained by the Chinese. Had they been allowed to remain for three years longer, even greater improvements would have been noted. But the Chinese are leaving the country and raw Kaffirs are coming to the mines. From the point of view of colored labor, the outlook for decreased costs is by no means favorable. If the raw Kaffirs would only stay on the mines for a few years, instead of months, it would be possible to get costs down, but soon after he learns his work, the Kaffir leaves for home, and the mine management must start with a new lot. The working costs in the future will vary with the ebb and flow of Kaffir labor.

What is often obtained only by strikes in other parts of the world has been freely given to the artisans on some of the mines, namely a reduction in working hours. Since the first of November, the working hours of mechanics and others employed on the surface of the mines controlled by Eckstein & Co. have been reduced from 56 per week to 51. Under the new arrangement the mechanics, carpenters, etc., commence work at 7 A. M. and continue until 12 M. An hour is given for lunch. In the afternoon they work from 1 P. M. until 5 P. M. These hours are for five days per week, and on Saturdays the men work from 7 A. M. until 1 P. M., receiving full pay for this short shift. The reduction of hours does not affect the mill-men, cyaniders, or engine-drivers, all of whom have had eight-hour shifts for years past. The concession has made a very good impression on the men, and it does not look as if the mines would suffer in any way.

The Central South African Railroads Co. is starting a scheme that well might be copied by the mines, namely the planting of large plantations of different kinds of wood, to produce 'sleepers' (ties) for the railroads in the future. South Africa, on the whole, is a forestless country, but it has been proved that most kinds of trees can be grown on the veldt. Were the mines to tackle this problem, there is little doubt that the Transvaal could in time produce all the timber required for underground work. It is difficult to get mining people to see the important relation between mining and afforestation. Trees planted today might benefit the next generation, but the motto

of mining too often is "Let posterity take care of itself."

On the whole the results from the mines for October are satisfactory. The total output from the Transvaal was declared to be 553,553 oz., valued at £2,351,344, of which the Rand's contribution was 532,933 oz., valued at £2,264,010. The October output falls short of the record by 1474 oz., and there seems little doubt that the high-water mark of the Rand output has been passed. As the outcrop mines die out, the output of gold will become less and less. No deep levels seem forthcoming to take the places of the star outcrop companies.

The Robinson Gold Mine takes the lead in October, with an output of 25,298 oz.; the Simmer & Jack is second with an output of 25,068 oz.; third on the list comes the Robinson Deep, which turned out 19,708 oz. The amount of waste rock sorted out does not appear to be as high as formerly. The Consolidated Langlaagte mine apparently finds it cheaper to do away with sorting and crush everything that comes from the mine. The Lui-paards Vlei Estate again takes the lead as far as duty per stamp is concerned. They report the very high figure of 8.8 tons per stamp per 24 hours. Next to this figure is that of the Glen Deep, with a crushing per 24 hours of 7.59 tons. The influence of tube-mills is readily seen in the far higher stamping duty now attained on the Rand.

London.

Progress in Cornwall.—Reopening Old Mines.—Difficulties in Pumping.—Geological Studies.—Age of the Formation.—Tin and Copper.—Methods of Dressing.—Wifley and Wetherill.—The Elmore Process.—Good Results.

The unwatering of the old mines in Cornwall, which are being reopened, is giving a great deal more trouble than either Cornishmen or outsiders expected, and is accountable for much of the delay in increasing the output of tin. It is usually supposed that Cornishmen look askance at new inventions and new ideas, but this is quite a mistake. When making designs for a plant to unwater the old mines, they listened quite readily to the representations of the makers of electric turbine pumps, and a number of these pumps have been installed. At Tywarnhaile the first electric pump put down in the Duchy gave a great deal of trouble, and after more than a year's work, is still not exactly satisfactory. The Parbola mine and Great Wheal Busy are suffering even more. At Parbola they have spent double what five previous companies spent at various times in reopening the mine, and they have not reduced the water-level more than a hundred feet. At Wheal Vor, which is being reopened by the Dolcoath people, the experience with electric pumps has been very sad, and already £33,000 has been spent and nothing done. The pump-makers admitted eventually that their design was an entire failure, and they are supplying a new plant to take its place. Of course, the whole of the above named sum was not spent in pumping. A good deal of the expenditure has gone in clearing out old shafts and levels, and in erecting machinery and dressing plant. The Cornish mines offer other water difficulties besides those that come in the wake of unsatisfactory electric pumping installation. In reopening some of them it has been found that pumping makes hardly any impression on the water. The slates are so fissured, and old workings are so interconnected, that the water is more like an underground lake of great area. Some years ago a fortune was spent to no purpose in trying to unwater some mines near St. Day. It was found that the pumps were trying to drain an area of twenty square miles.

While writing about Cornwall, it is of interest to men-

tion that the new Geological Survey maps and memoirs of Western Cornwall have been published during the current year. There are three volumes of memoirs. One deals with the district that includes Land's End, Penzance, Marazion, and St. Ives. A second covers the district from the Lizard and Falmouth to Camborne and Redruth, and a third includes the district of St. Agnes. The surveys and investigations have been made by Messrs. J. B. Hill, Clement Reid, J. B. Scrivenor, J. S. Flett, D. A. MacAlister, and others. The books are naturally of great interest, especially at this time when Cornwall has in the past suffered from the absence of detail in the studies of its rocks on the part of the Geological Survey. In the old days, geologists were almost solely paleontologists and the geology of a district like Cornwall, where no fossils are found, did not hold out any attractions. The old Geological Survey never seriously tackled the rocks west of Devonshire and Plymouth districts. The slates of those districts were studied and placed in the Devonian series and, without any serious investigations, the slates of West Cornwall were thrown in with them. The present Survey remedies this state of things. The slates, or killas, to give them their local name, have been moved farther down the table and put provisionally among the Ordovician series, though naturally the entire absence of fossils makes it difficult to place them exactly. The Survey, on the other hand, has deemed it best not to depart from the word 'greenstone,' or to give this intrusive rock any more modern name. The word still describes the rock in the most useful way. The memoirs give interesting accounts of the contorted killas, the intruded sills of greenstone, and the subsequent intrusions of the granite, the elvan dikes, and the mineral veins. They also give a good deal of information about the metaliferous lodes, but not sufficient to satisfy a mining man. It is stated: "The mines are now to a great extent worked out and abandoned." I am inclined to join issue with the geologists with regard to the words "worked out," and to ask for more specific evidence to support this somewhat drastic judgment. My own experience of abandoned mines in Cornwall is that they were abandoned not because the ore deposit had given out, but for other and different reasons. In fact, I do not know any tin lode that has given out in depth. The old Cornishman worked a lode as long as he could find a clean tin ore or a mixed tin and copper that could be separated by hand. The separation of tin and copper could not be effected mechanically in those days. If wolfram came in, the deposit was abandoned. Unless the tin or copper was of a certain grade, developments were soon discontinued, for there was not sufficient capital to work low-grade ores on a large scale or to bridge over periods of unprofitable returns. In many cases, work had to be abandoned because a depth had been reached where new hauling and pumping plant of greater cost than they could afford became necessary.

It will be seen from these remarks that it is difficult to generalize on the subject of abandoned Cornish mines. No records were ever kept by the old miners and the exact circumstances of the abandonments cannot be ascertained. It is just this uncertainty that makes their reap-

ening a more risky speculation than developing new prospects from the surface. It is readily admitted that the richer deposits of tin and copper near the surface are worked out, but there are left behind great quantities of complex ores, useless at one time, but now amenable to treatment. A mixed ore of tin, arsenical pyrite, and copper pyrite, could not be treated on the old buddles, but the Wildley table gives a very good separation. Similarly, tin could not be separated from wolfram. This is remedied by the provision of the Wetherill magnetic separator, and though as yet the separation is not thorough, mixed ores that were formerly useless are now being worked at a profit. What promises to be the most valuable process for Cornwall is the Elmore vacuum-flotation process and it would not be surprising to find that it solves a good many knotty problems of ore treatment. A plant is in operation at Dolcoath, where some complex ore that has been exposed in the upper levels for decades is being treated with most interesting results. The ore is a mixture of pyrite and other sulphides containing 2 or 3% copper and some arsenic, together with

from 10 to 20 lb. black tin per ton. It is treated first in the vacuum plant, which removes over 90% of the sulphides and produces a concentrate containing 15 to 20% copper, together with the arsenic. The tin is unaffected and passes out in the tailing. The concentrate is first burnt to remove the arsenic and is then disposed of as copper ore. The tailing containing the tin goes to the dressing floors. This ore contains no wolfram. Any wolfram in the ore would pass away with the tin in the tailings and would be recovered with the tin, and the mixture would be separated in the Wetherill plant. In this way it will be seen that an ore containing tin, wolfram, copper, and arsenic, would be perfectly amenable to treatment. At South Crofty there are ores of this sort, but by their system of dressing a good deal of the iron from the pyrite is removed in the magnetic separator. This introduces a complication in separating the tin from the wolfram and makes the study of the machine all the more difficult. For some reason the tin has a way of going with the wolfram, and the engineers allege that it is the iron in the mixture that is the cause. If this is the true explanation, the provision of a vacuum plant would obviate the drawback, for practically the whole of the iron would be removed before the tin and wolfram mixture went to the magnetic separator. It is possible that the presence of iron is not the true or the whole reason for the tin going over, but that the eddies of air set up by the two belts traveling past each other so close together may contribute to the extraction of some of the

tin with the wolfram. In any event the previous extraction of the iron by an entirely different process would improve the treatment.

Butte, Montana.

Ore Production of Boston & Montana.—The Washoe Plant Idle.—Rich Ore in the Lizzie.—Butte & London.—Barnes-King Fiasco.—Suit to Be Brought.—Surprise Eagle.—Gold Mining.

Although the Amalgamated company has been transferring its working forces to the mines and smelter of the Boston & Montana Co. since the closing of all its other mines, the Boston & Montana is not yet producing to its full capacity, and probably will not for some time yet. The ore production of that company has been more than doubled, but its capacity is about 3600 tons per day. The December copper production of the Butte mines will be about a million pounds less than in November, but the loss is likely to be made up in January. The Washoe smelter at Anaconda has been closed tight, and that city, which depended almost entirely on the smelter for support, is suffering the brunt of the shut-down. The outlook for an early resumption of operations at the mines is not good. An official of the Amalgamated says the only influence that prompted a shut-down and a concentration of operation and expenses in the Boston & Montana Co. was necessity. He says the smoke suits pending against the Washoe smelter had nothing to do with it. The company was losing a great deal of money in keeping both large smelters running, as the cost of production was greatly increased under the curtailed operation. By transferring all production to the Boston & Montana that company's mines and smelters can be run to full capacity, the cost of reduction can again be reduced to the normal, and the company can make some profit at present copper prices. The fact that the Clark mines have also reduced their output fully 50% is cited as evidence that curtailment and economy are the causes of the Amalgamated shut-down. The people of Butte and Anaconda are feeling very blue over the situation.

The rich vein of copper ore found in the Lizzie claim by lessees has been developed and is found to grow in importance as exploration proceeds. It is accepted as certain that the vein will be found large and immensely rich at sufficient depth. The Lizzie claim is owned by the Davis-Daly Estates, and it is reported that the company expects to be able to resume development work on the Colorado claim, which is near the Lizzie, and to develop the veins in the latter ground from the 1000-ft. level of the Colorado. The Davis-Daly, like many other new companies, has been compelled to suspend exploration and development work because of the financial stringency, but the managers have hopes of raising money soon with which to resume work. It has been stated that the Davis-Daly had a considerable sum of money tied up in the suspended State Savings bank of Butte, but the report of the State bank examiner shows that the company has only \$7750 on deposit in the bank, though the vendors of the property, who organized the company and contracted to furnish a fund for the Davis-Daly Co., have \$45,500 on deposit.

The Butte & London Co., one of the well managed and well financed new companies, is still prosecuting exploration work on the 1100-ft. level of its property. Three veins have been cut and drifts are being advanced on two of them. Both are well mineralized, and H. V. Winchell, consulting engineer to the company, has advised a continuance of the driving, for, in his opinion, commercial ore will be found in at least one of the veins. Cross-cutting is also being continued and will be carried to the limits of the company's ground, which is 1500 ft.

in each direction from the shaft. The company is still well supplied with funds and expects to be able to continue exploration work until money conditions improve and new funds are available.—The Colusa-Leonard Extension Co. has practically stopped development work in its property, but it has opened a fine vein with a 14-in. streak of high-grade ore in a lode seven feet wide. When money conditions get better the company will sink the shaft, which is now 800 ft. deep, to a depth of 1500 feet.

The directors of the Barnes-King Development Co. have replied to a demand from a large number of stockholders that suit be brought against the promoters and underwriters to recover money alleged to have been obtained from the subscribers by fraud, and the board has signified its intention to comply with the demands and bring such a suit in the name of the company. It is understood that details are now being gathered for that purpose and that some attorney who is not a stockholder

Montana.

and who has never acted as attorney or counsel for any of the big parties interested in the Barnes-King, will be retained to prosecute the case. The suit, if brought, will be against the New York syndicate of underwriters, the A. J. Campbell estate, and the members of the first board of directors, as well as the Butte men who assisted in the flotation of the alleged fraud. The reports from the mines of the company grow worse instead of better, and it appears doubtful now whether the company will ever earn anything.

The Surprise Eagle Mining Co. has started work on the Morning Star mine, in Jefferson county, five miles east of Boulder. It has a shaft 200 ft. deep, from which considerable high-grade silver ore has been mined above the water-level on a vein 14 in. wide. The company also owns several other properties in Jefferson county and a full claim in the Butte district, upon which a vein of copper ore, 2 to 6 ft. wide, has been opened.

About the only mining that is done in Montana at a good profit now is in the gold mines and placers. The Southern Cross Mining Co. has just made another clean-up, the second in two weeks, and has shipped to Butte two bricks, one weighing 24 lb. and the other 11 lb. The company has built a mill and cyanide plant. The shaft on the Southern Cross is 200 ft. deep, and the orebodies have been opened at that depth by cross-cuts and drifts. It is claimed there is enough ore to keep the mill running for four years, the mill having a capacity of 100 tons per

day. The stamp-mill has been rebuilt. The cyanide plant is equipped with all the latest appliances, including the Moore filter for treating the slime. The company has expended about \$100,000 on its mill. Before the company took hold of the property lessees had worked it and taken out \$350,000. Until the adoption of the Moore filter the company experienced great difficulty in saving the gold, as it went off in the slime. It is claimed by the company that the Southern Cross ore now being mined assays on an average about \$8 per ton in gold.

Salt Lake. Utah.

Smelter Smoke and Farmers.—An Adjustment by Blackmail.—The Tintic Smelter.—Garfield Concentrator.—Lowering of Wages.

At this writing it is not known whether an agreement will be reached between the management of the Utah Consolidated and the farmers of the Salt Lake valley respecting the operation of the Highland Boy smelter until March 1, 1909. However, there are prospects of an understanding being reached, in which event a stipulation will be filed with the Court for a modified decree permitting the smelter to be operated during the period stated, which would give the company sufficient time to construct its proposed new smelter in Tooele county. First the farmers demanded a bonus of \$175,000; the directors of the Utah Consolidated offered to pay them \$100,000 and in addition make good any damage that might accrue to vegetation; this the farmers refused to accept but they came back with a second proposition expressing a willingness to split the difference in the matter of bonus. The matter was then passed up to the directors of the company for the second time, and this time for final disposition. Should the proposition be turned down, the smelter will close as soon as the injunction of the Court becomes operative; while on the other hand, if the compromise is accepted, it will mean that the plant will continue in operation for another fifteen months or until the date stated. Based on a bonus of \$100,000, the plaintiffs in the smoke case would draw down approximately \$7.50 per acre on their lands, situated within what is known as the smoke zone.—The smelter of the Bingham Consolidated is all but closed and the fires will be totally extinguished by the end of the present week. The Bingham smelter was the second copper plant erected in the Salt Lake valley and is the first one to go out of business as a direct result of the decision of the Federal Court in the smelter smoke case. It is also probable that the United States copper smelter will also be closed, as has already been announced by the management of that corporation; however, it is not improbable that some arrangement will be made like that of the Utah Consolidated, provided the latter is successful in its negotiations.

The Ohio Copper Co. has filed a copy of its articles of incorporation with the Secretary of State. The organization is capitalized for 1,000,000 shares of the par value of \$10. The company's properties are situated at Bingham.—The aerial tramway of the Tintic Mining & Development Co., at Bingham, has been placed in operation, and hereafter the ores of the Yampa mine will be transported direct to the smelter at lower Bingham.—The building of the new lead-silver smelter of the Tintic Smelting Co. is to be pushed as rapidly as possible. Jesse Knight, one of the leading spirits in the enterprise, says the plant will be ready in April, and that a large portion of the equipment is now on the ground.—The Garfield concentrating mill of the Boston Consolidated Mining Co. will be started toward the end of the week. Three sections of the plant are ready. Each section will treat 500 tons of ore per day.

The ore shipments from the Tintic district last

week amounted to 91 carloads, the contributing mines and respective amounts being: Bullion Beck, 3; Carisa, 1; Centennial Eureka, 50; Colorado, 1; Eureka Hill, 3; Mammoth, 8; May Day, 2; Scranton, 4; Tetro, 1; Tintic Iron, 10; Yankee Con., 8 carloads.

Denver, Colorado.

Coal Strike Ends.—The Drainage Adit Resumed.—Doyle and Burns.—In the San Juan.—Christmas Dividends.

The local coal strike has been declared off by the officers of the United Mine Workers of America. The union, although successful in making its point against the wagon mines, could not force the mines that shipped by railroad to accede to its demands. The wagon-mine operators, seeing the situation as it really is, have cut wages nearly to the former schedule. The unimportance of the field and the condition of the labor market made it useless for the union to continue the strike.

Arrangements have been made between the Cripple Creek Deep Drainage Tunnel Co. and W. M. Bainbridge, superintendent of the El Paso mine, by which the latter as an individual is to continue the work on the adit until the Tunnel company can let a new contract. The specifications of the new contract are practically the same as in the first. The adit must be pushed at the rate of not less than 750 ft. every three months until the intermediate shaft has been sunk to the adit level. When this is done, work is to be pushed both ways from the shaft and also from the portal end at not less than 1500 ft. for every three months until connection is made with the portal. The intermediate shaft is 8000 ft. from the portal of the adit and is now down 90 ft. The contract specifies that the remaining 600 ft. shall be sunk and timbered at not less than 209 ft. for every three months. The tunnel is to be continued 7 by 10 ft., as at present, or it may be of circular cross-section, 8 ft. in diameter. This last condition makes it possible to entertain a bid from a Denver firm having a newly patented tunnel-boring machine. A forfeiture clause is inserted and the contractor has to give a \$20,000 bond on the adit work and a \$5000 bond on the shaft.

James Doyle has scored a new victory in his long-standing and now famous suit against James F. Burns, of Colorado Springs, for the recovery of \$447,000 worth of stock in the Portland Gold Mining Co. Doyle alleges that this stock, which is rightfully his, was withheld from him by Burns. The suit has had many sensational turns during the past six years, and promises to be dragged through the courts until the Portland Gold Mining Co. has ceased to exist. The new trial allowed to Doyle will be started at once in the District Court at Council Bluffs, Iowa.

Of the mines in the San Juan district only the more profitable are being operated. Among the most important to be closed for the winter are the San Pedro, Gold Prince, Aspen, Champion, and the Detroit & Colorado. The closing of these mines has thrown about 350 men out of employment. Most of these have left the district in search of work elsewhere. On Dec. 20 the Propatria mill at Rico was put in operation, and the whole town took occasion to celebrate the event. The mill has a capacity of 100 tons per day, but, owing to the low price of the metals, only 50 tons per day will be treated until prices improve. The United Rico Mines Co. has fully a year's supply of ore developed for the mill.

Many of the Cripple Creek companies paid extra Christmas dividends to their stockholders. The Work M. & M. Co., the Elkton Consolidated, and the British American Mining Co. each made the extra dividend one cent per share.

Torreon, Mexico.

The Peñoles Mines. — Picturesque Engineering. — The Smelting Plant.

The general offices and smelting plant of the Peñoles Mining Co. are at Mapimi, Durango, situated some 20 miles westerly from Bermajillo station on the Mexican Central. The narrow-gauge railroad extending from Bermajillo to Mapimi is the property of the Peñoles company. The company's mines are high up in the limestone hills about six miles distant from the smelter. A 36-in. gauge railroad connects the smelter with the mines, the centre of the mining operations being known as Ojuela. The last mile or two of this railroad, that extending from the foot of the hills to the mines, is a cog-road having a maximum grade of 14%. Hauling supplies and ore over the latter section is done with a powerful walking-beam rack locomotive engine, which is of the Abt type and a Swiss patent. This engine makes 18 trips per day over the cog section, hauling four cars of ore, or 30 to 40 tons at a trip. The principal ore-bins are at the upper terminal of the cog-road. The cars, passing under the chutes, are loaded by gravity. Tracks from the different shafts centre at these ore-bins. In order to transport the ore from one of the main shafts, a suspension bridge, having a 1,030-ft. span, was built across a deep gulch to support the track. The vast silver-lead orebodies, which occur as chimneys in the lime, are opened by six vertical shafts and a number of winzes. There are 18 levels connected with the shafts. The deepest workings extend to about 3,000 ft. in depth.

The ores are both oxides and sulphides and the line of demarcation between the two is somewhat variable in different parts of the property. In general, it is claimed the sulphides are first encountered at a depth of about 1,750 ft. The minerals in the ore include arseno-pyrite, galena, sphalerite, fluorite, hematite, barite, cerussite, anglesite, and calcite. Approximately, the contents average 17% lead, 20 oz. silver, and 0.2 oz. gold per ton. The exploratory work is entirely with diamond-drills, of which there are now 17 in operation. In this work the ground is blocked out 120 metres square and 60-metre horizontal holes are driven with the diamond-drills from opposite sides. This is the deepest mine in Mexico and some of its old workings are said to date back to the middle of the sixteenth century. The Peñoles Mining Co., controlled by capitalists at Frankfurt, in Germany, began operations here in 1893. For the year 1906 the ore hauled from the mine to the company's smelter amounted to 140,000 tons. At present 1,100 men are employed at the mines.

The smelting plant contains six water-jacketed blast furnaces, each 46 by 162 in. at tuyeres, and 21 ft. 6 in. high, the capacity of each furnace being about 150 metric tons per 24 hr. The furnace charge contains 20% silicious ores which are purchased and shipped in from outside mines, as the Ojuela group produces no silicious ores. An electric crane is being completed to handle the slag in 6-ton units to two reverberatory matte-separators, each of 1,000 tons capacity of material per day. The furnaces are now fed by hand, but early in 1908 the charge will be made up from 10,000-ton storage-bins into 4-ton units of charge and hauled by electric locomotives over steel trestle-tracks to hopper-bins above the furnaces, supplanting hand by mechanical feeding. The bullion is taken liquid from the furnaces to three 45-ton drossing-kettles in which it is purified for casting into bars for shipment to refineries. The blowing machinery consists of two No. 10 Connorsville blowers, direct connected to a Rice & Sargent tandem-compound steam-engine; and a

Nordberg engine does similar duty. They have five No. 7 blowers in reserve. The plant also contains a Huntington-Heberlein converter apparatus of twelve 10-ton pots, which are operated in connection with six Wethey roasters. This roasting and converting plant reduces the sulphur in the sulphide ores that come from the lower mine levels before it goes to the blast-furnace charge. The operating staff of the Peñoles company is as follows: General manager, Kuno B. Heberlein; superintendent of smelter, H. S. Mulliken; superintendent of mines, O. R. Whittaker.

Denver, Colorado.

The Newhouse Tunnel.—The Cripple Creek Strike.—Survey Work at Aspen.—The State School of Mines.

The famous Newhouse tunnel has been connected with the shaft of the Old Town mine. When the connection was finally made on Dec. 8, Idaho Springs celebrated by ringing of bells and blowing of whistles. To accomplish this engineering feat the adit had to be driven 14,900 ft. and a lateral extended 1326 ft. The connection was made 2184 ft. below the collar of the Old Town shaft, where a station has been cut and bins got ready for the ore that is to be shipped through the adit at the earliest possible date. During the last year the lateral was driven 2192 ft. and the Old Town shaft sunk and timbered 586 ft. H. Brown, the surveyor who has had charge of the engineering work, deserves credit for the close connection finally made.

W. D. Haywood, secretary of the Western Federation of Miners, has at last officially declared the Cripple Creek strike to be at an end. While it is recognized among mining men that this action will have no effect upon the present conditions at Cripple Creek, it is of advantage to the members of the Federation. They may now go to this district and apply for work. The trouble at Goldfield is evidently the reason for calling off this protracted strike. As far as Cripple Creek was concerned, the strike was practically settled when the organization known as the Western Federation of Miners was driven from the district after the Independence depot outrage in June, 1904. The recent trials of Moyer, Haywood, and Pettibone in which Harry Orchard's testimony has figured so prominently have served to refresh the memories of the Cripple Creek operators. The Federation need not expect to gain a foothold in this camp again, as the card system is being rigorously enforced just now by men who have had a bitter experience.

The operators and prospectors of Aspen have taken notice of the project to ask the U. S. Geological Survey to make a map of Summit county, and a petition is now being circulated at Aspen. The district has outgrown the original geological map, and there is need of some more work being done there, especially to the south.

The annual report of the Colorado School of Mines has been submitted to the Governor. The report shows the school to have passed a very prosperous year. The \$35,000 set aside by the Legislature last April has been partially expended on the new building, which is to contain the offices, gymnasium, natatorium, and club-rooms. Graduate courses in mining and metallurgy have been added to the curriculum; 329 students are in attendance of which 58% are registered from Colorado, which makes them free as far as tuition is concerned. After September, 1908, the tuition will be raised from the present rate of \$100 to \$150. Notable features in the report are the plans for a very complete testing plant to be built as soon as the funds can be secured, and the opening of a real mine as a laboratory for the students. This is the first mining school to have such a mining laboratory.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

THE STAMPS at the new 300-stamp mill at the Simmer Deep property weigh 1,750 lb. each, this is 500 lb. above the average weight of stamps on the Rand.

IN Sonora, the Douglas Copper Co. is using traction engines successfully, making trips of 50 tons each. Four outfits make the round trip of 20 miles each way in 2½ days, from Cobre to Fundición.

THE SHAFT-SINKING record at Butte, Montana, for a three-compartment shaft is 125 ft. in 30 days. This record was made at the Pilot-Butte shaft in November. The country rock at Butte is a granite.

ROPE for transmitting power has displaced gearing and belting in a great number of installations. The cause of late acceptance of this cheap and ready method was the lack of reliable and sufficiently flexible rope of reasonable endurance.

RECENTLY an electro-chemical method has been perfected whereby atmospheric nitrogen is oxidized to nitric acid. It is used in Norway where nitrate of lime and soda are being manufactured at the rate of 1000 tons per year. This nitrate of lime is said to constitute a superior fertilizer.

THE countries possessing the best mines of arsenic are: Germany, England, Austria, France, Italy, Spain, Portugal, Norway, Siberia, New Zealand, Chile, Mexico, Canada, and the United States. Germany produces the largest quantity of metallic arsenic and arsenious acid. England held first place in 1902, but has fallen far behind. The United States consumes more than one-half of the world's production of metallic arsenic.

THE ore sent to the 100 stamps in the mill of the Batopilas mines, in Mexico, ranges from a minimum of 4 oz. to a maximum of 10 oz. silver per ton. The silver is mostly in a free condition, that is, native. The stamps are light and crush one ton per day, the pulp being concentrated before another amalgamation treatment, while the tailing from this amalgamation goes to roasting furnaces and hyposulphite leaching vats. The mill is run by water-power, and the company is blessed with a mechanical genius and a machine-shop. That is why 4-oz. silver ore can be handled profitably.

A LARGE DEPOSIT of vanadium sulphide ore has been opened in Peru. Mining conditions are easy and the ore is transported to the port of Callao. Five large veins have been proved on the property. Vanadium, which is used in hardening steel, has generally been referred to as a rare element; but it is very widely distributed, being a constituent of most clays. However, it could be produced in few localities and small quantities only. The development of the Peruvian deposit and the erection in Pittsburg, Pa., by the American Vanadium Co. of works having a daily capacity of 2000 lb. of vanadium alloys seem to settle the question of commercial supply.

POTASSIUM CYANIDE is rapidly decomposed by water containing large amounts of mineral matter; but frequently such water must be used in cyanidation. This decomposition of cyanide is easily overcome by using a proper amount of alkaline re-agents. The effect of soluble salts of aluminum, calcium, and magnesium is to

destroy the cyanide not only directly, but also indirectly; they destroy the protective alkalinity, which fact allows even carbon dioxide from the air to decompose the cyanide; they directly act upon the cyanide itself, as the following formula indicates: $\text{MgCl}_2 + 2\text{KCN} + 2\text{H}_2\text{O} = \text{MgO}_2\text{H}_2 + 2\text{HCN} + 2\text{KCl}$.

THE use of wood in smelting copper-sulphide ores has been fairly successful at the Mitchell Mining Co.'s mines in Guerrero, Mexico. In operating a 200-ton smelting plant, it was endeavored to dispense almost entirely with the use of coke, pending the construction of a railroad. Various experiments with one-third oak blocks, one-third charcoal, and one-third coke were not very successful. Using two-thirds wood and one-third coke, the product was a matte of about 28 to 30%, whereas with a full coke charge the furnace made a matte of about 40%. By dipping the wooden blocks in a thin paste of silica and clay a much higher concentration was obtained, making a matte of 38%. After securing that excellent result the company continued to smelt with wooden blocks alone, but did not get from the furnace the full smelting capacity that it would with the full coke charge.

ARTIFICIAL abrasives suitable for grinding purposes were unknown before the invention of the electric furnace; but the manufacture of alundum was begun by the Norton Emery Wheel Co. of Worcester, Mass., in 1904. Its chemical composition is the same as that of natural corundum. The process of making it consists in taking the mineral bauxite, purifying it and melting in an electric furnace into a large homogenous mass. Upon cooling this molten fluid crystallizes in solid masses of alundum of great purity and uniformity. After crushing and sizing it is manufactured into grinding wheels and blocks, polishing stones, etc.; the powder is used for cutting and drilling rubies and sapphires for watch jewels. The production of alundum has been as follows: In 1904, 4,020,000 lb. valued at \$281,400; in 1905, 3,612,000 lb. valued at \$252,840; in 1906, 4,331,233 lb. valued at \$303,186.

THE freezing process sometimes employed in shaft sinking consists in building a wall of ice around the shaft from the water from which trouble otherwise would arise. The ice cylinder must be sufficiently strong mechanically to withstand the stresses brought against it by the working of the ground, the motion of the water, and sinking on the inside. No rule can be given as to the thickness of the wall, as many variable factors enter into the equation. The temperature must be reduced to a considerable number of degrees below freezing point. The refrigeration is effected by a ring of vertical pipes fixed in the ground and containing water to be frozen. The tubes are placed usually from 3 to 4 ft. apart, the number varying with the diameter of the ice cylinder to be formed. The freezing arrangement consists of two concentric tubes; the bottom end of the outer one is closed and the bottom end of the inner one is sometimes fitted with a strainer to prevent the passage of grit. The greatest difficulty of the process is in the fixing of the tubes in an absolutely vertical position. Where rock or clay has to be passed through, holes are drilled, or bored with a sharp-edged tube; they are lined with guide tubes, inside of which the freezing-tubes are fixed. The inner tube is usually from 1 to 1½ in. in diameter; the size of the outer tube will vary with the depth, thickness, and diameter of the ice cylinder for the cooling action of the pipes (in which cold brine is circulated) is proportioned to the surface of pipe exposed to the stratum and the water contained in it.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Assessment Work.

The Editor:

Sir—In our ramblings for a prospective mine, hardship, privation, and uncertainty, with which is included financial stringency, are constant troubles always with us, none of which have as yet prevented the performance of annual assessment upon promising showings. In my experience, supplies have always been forthcoming in sufficient quantity to enable one to do his annual representation work whenever the value of the showings warranted it. The failure of a person to get necessary supplies, to enable him to perform his assessment work, indicates characteristics foreign to the real prospector. Such a person, if examined closely, would most likely be found to belong to the class known as 'locators,' men that run pell-mell into the field of new discoveries and locate everything in and out of sight, with the aim of sitting back and selling on the strength of proximity to the original discovery, upon which the discoverer is rarely found wanting, in doing his assessment and demonstrating real values. The prospector has mostly performed his assessments by this date, and most likely is suitably located for trapping, drifting, sluicing, or rocking a few dollars out of nature's bank to carry him over the year 1908.

JAMES BRINDLEY ROWLEY.

Galice, Oregon, December 6.

Hang-Fire.

The Editor:

Sir—In your issue of November 9, under 'Concentrates', you mention that there was practically no danger of hang-fire where electric blasting was used. Several instances, in railroad work, have come to my notice where charges of black powder have hung fire when exploded with the electric battery and a few sticks of dynamite. On the Columbia Falls North line of the Great Northern an assistant engineer was killed from this cause. Two pockets had been loaded with about ten kegs each of black powder, and but one pocket went off on time, the second one hanging fire about five minutes. The engineer had thought that the danger was over and started to go over the cut when the second pocket exploded. The reasons advanced for the accident were that there was not enough dynamite used as an exploder or that the charge was loosely packed and the dynamite served only to set fire to a train of black powder, which had to burn to the packed charge before the same would explode.

F. T. HOWES.

Scott, Wash., November 21.

A Sampler.

The Editor:

Sir—In your issue of November 9, Mr. C. Y. Knight, by means of a letter published in your journal, made known his want of a sampler for wet sand, and since no answer from dealers in cyanide supplies has yet been printed I presume that such an article is not on the market. The question interested me, not only because I have for a long time considered the sampler described to be a very accurate one, but because there are still in use (in various cyanide plants) samplers of the whole or part tube type.

It is a well known fact in gold and silver cyanidation

that the extraction in the different horizontal layers of sand decreases with the depth of the layer, so that the top part of the vat represents the layer of best extraction and the bottom the lowest. I know of no sampler other than that of the screw type described by Mr. Knight that is capable of giving a perfect sample of wet sand in place, and by its use over a period of several years I have seen the theoretical figure for the extraction obtained from headings and tailings of sand come within 1 or 2% of the actual extraction obtained from headings of sand and bullion produced.

On the other hand, I have seen gross discrepancies in these figures as the result solely of the use of poor samplers. These results are often wrongly attributed to solution leakage, vat absorption, theft, etc. These samplers are fragile and hard to make and the best plan is to always have an extra one in stock ready for emergency.

I do not believe that they are on the market, at least I have never seen them, but there should be a good sale for them, and it is up to the dealers to get busy.

FRANK W. OLDFIELD.

Los Angeles, December 5.

Prospecting With the Diamond-Drill.

The Editor:

Sir—I have seen several articles in mining journals in which the writers have asked whether the richness of the ore will increase or pinch out, as a greater depth is reached, in the mines of Goldfield. I have heard the same question asked by many people. I ask the question, why don't some of these enterprising companies find out?

Why not use a diamond-drill to sink a bore to a depth of 4000 or 5000 ft. or several bore-holes to get complete results? The information so obtained would prove interesting and possibly surprising. Dozens of holes have been sunk to depths ranging from 4000 to 5000 ft. on the Rand in South Africa. One hole was bored at Doornkloof near Randfontein to a depth of 5560 ft. in 14 months, working 24 hours per day; extracting a core of 2 in. down to 700 ft.; in drilling the remaining 4860 ft. a smaller sized bit was used, removing a 1½-in. core. Another hole with a record of 5582 ft. was completed in 9 months, and still another hole was bored near Johannesburg to a depth of 6340 ft. The mining companies there were of the engineering type. They wanted to know, when the shallow workings were exhausted, if the reef persisted at greater depths, and if so, whether it was worth the heavy expense of sinking an operating shaft to these depths. The diamond-drills have answered their questions in the affirmative, prolonging for a long time to come the existence of that important mining field. It is up to some of the Nevada districts to do the same and answer these questions.

I doubt if there has been a half dozen holes bored to a depth greater than 2500 ft., and I have no knowledge of any diamond-drill hole in North America to a greater depth than 3000 ft. I also wonder why it is that the drills have not been used to a greater extent than they have in this country. The mines on the Mother Lode in this State have merely scratched the surface. The Kennedy is (as far as I know) the deepest mine. The owners of one mine spent ten years looking for pay-ore, which they could have found long ago by the systematic use of a diamond-drill. Another mine in the same locality, sank a shaft 1900 ft., cross-cutting every 100 ft., spent \$1,000,000 and took out \$25,000 worth of ore. This mine today is for sale for a song. I firmly believe there is good ore to be found on the property. A good

prospecting with a drill would have proved the ground to a greater depth and at a cost of \$25,000 or less, as against \$1,000,000. I venture a prophecy: At some future time the Mother Lode of California will be re-prospected and abandoned properties will again be producing at a much greater depth.

To a man who has followed the diamond-drill in various countries, geological reports are very misleading and inaccurate when taken from surface indications; for surprising results are obtained from holes 100 ft. apart. The successful operation of a diamond-drill is assured with an experienced and intelligent foreman, who insists that he shall get core. Why don't some of the successful men who have made their wealth in Nevada, do some deep prospecting on their properties? or do they fear the results obtained from a greater depth?

E. G. TINNEBO.

San Francisco, December 18.

Wall Street.

The Editor:

Sir—In your issue of December 7, a letter from Mr. A. G. McLaughlin defends Wall Street from the implication that it is a gambling centre. Mr. McLaughlin's statements as to banks and financial centres are true enough, but they do not seem to me to throw much light on the question whether or not Wall Street is a gambling centre; and the points he makes in the latter part of his letter are not convincing.

To discuss this question satisfactorily a mutually agreed upon definition of gambling seems necessary. Whole volumes on political economy seem not to have been able to define beyond cavil what constitutes the difference between gambling and legitimate business; between a speculation and an investment; but on Mr. McLaughlin's own understanding of gambling as "the act of hazarding wealth upon mere chance; as opposed to hazarding wealth upon mature judgment," I take issue with him and maintain that most of the trading on Wall Street is mere gambling. Which is to say, that the results of hazarding wealth on Wall Street, whether by piker or plunger, producer or parasite, to all practical intents and purposes, are determined mainly by chance.

The openly admitted purpose of nearly all these traders is to make not only a profit but a quick profit, an easy profit, and a big profit; one that is made so quickly that mature judgment seems absurdly out of place in the deal, one requiring no work for its making, and so big as to be out of all proportion to profits considered excellent in average business. The ignorance of many operators on Wall Street in regard to the corporations in whose securities they deal is such that they could tell little else of those companies than that the stocks had fluctuated thus and so in the past. They buy and sell on tips, rumors, advertisement, inside information, outside misinformation, past performances, and even 'hunches.' As for ninety days: why, the trader has got to get action on his money in less time than that if he has to sell at a loss and try something else. Did Mr. McLaughlin never meet a specimen of the genus 'tapeworm' who has "to speculate daily or die?" His name may not be legion, but in New York it is at least battalion.

The great majority of the clients of New York Stock Exchange brokers have businesses outside of Wall Street, and the buying and selling of stocks is much such a diversion to them as is poker or the ponies to the devotees of those games. Though the 'tiger' little suggests the tabby, still they are both cats. The only essential difference is in size.

As a common market-place for the convenience of those

who wish to invest in, or dispose of, the commodities there dealt in, Wall Street unquestionably has a justifiable reason for existence; but the great volume of business done there is maintained by those who are playing a game for stakes, and the influence of mature judgment as a factor in the operations is conspicuous only by its absence. My position in this is similar to Mr. McLaughlin's in that I have never purchased a security on margin nor ever traded in a bucket-shop, though I have worked for years in New York near Wall Street and have watched the game with interest from the outside. I speak merely as a man who believes in facing facts as they are.

ALBERT L. CLARK.

Long Beach, Cal., December 11.

Drill-Sharpeners.

The Editor:

Sir—In 'Concentrates' of December 7, the statement is made that hand-sharpened drills last longer than machine-sharpened drills, presumably for the reason that hand-sharpened drills get more hammering than do the machine-sharpened drills. I want to call your attention to a few facts bearing upon this matter.

To sharpen a cross bit by hand the process is as follows: In order that the drill may work easily, it is first heated to as high a heat as it will stand; then each corner is drawn out by means of a thin-edged fuller, this takes from 3 to about 8 blows from the helper for each wing, then the quarter dollie is applied to each wing and from 2 to 5 blows are given each wing; then the side-set or flatter is placed on the side of each wing; 2 to 3 blows is all that is usually given to each wing on the side, then from 2 to 3 blows on the edge of each wing, as none of these tools cover more than one wing at a time, unless a full dollie that will cover all the wings of the drill is used. In that event not more than a total of 10 blows are delivered on the dollie to cover the whole face of the bit. From this it will be seen that the minimum number of blows given to each wing is 9 and the maximum is about 20; the smith that would ask his helper to deliver 80 blows on each drill would soon find himself without a helper, and he therefore does this work with 40 blows or less oftener than he does it more. It will be seen that each wing is a separate part of the drill and is treated separately, this would show that 12 blows would be nearer the average blows given to each wing. Some smiths will pound the edges with a hand-hammer to finish it, but these men are the exception rather than the rule.

Now let us suppose that the sharpening was being done with a Word drill-sharpener; I have watched men running these machines, first two of the wings are drawn to an edge as in hand-sharpening, each wing receives from 10 to 15 blows, in this part of the work, then the dollie is allowed to strike it. The dollie used in this machine covers only two wings of the bit at one time; the hammer will strike the dollie at the rate of 400 blows per minute, but it will not take over 50 blows on each wing to do the dollie work, it is then side-set and hammered on the edges to finish the job.

As either of the hammers will strike 400 blows per minute and some men will hammer the drill as long as a minute, while others will only hammer it half a minute, if in the former case you divide the 400 by 2 (as only two of the wings are subject to treatment at once) you have from 100 blows (for the man who sharpens a drill in half a minute on each wing of the bit) to 200 (for the man who sharpens a drill in a minute).

Now take the Numa, Eclipse, or Ajax drill sharpen-

ers, which use a full dollie or one covering the whole face of the bit, and allowing that the operator puts in the same amount of time, we find that in dollie work each wing receives at least half of the number of blows struck. We find that in the three machines just mentioned the actual number of blows given to each wing of the bit is a half more, or from 150 to 250; now placing the number of blows given a drill by hand-sharpening at the maximum, you have 80; and in the machine-sharpening method take the minimum number of blows given to the drill and you have a total of from 150 to 200, allowing for the fact that some men work slower than others. Comparing these figures with your statement that the steel is improved by hammering, it would seem that the machine-made bit would be the best. This not only appears to be the fact, but it is the fact; machine-sharpened drills get from 2 to 5 times as much hammering as hand-sharpened drills. In tests made by me I have found that machine-sharpened drills would do more than twice as much work as hand-sharpened drills. To cite one instance, at the Homestake mine when I was there with my first machine, a smith was instructed to make a starter as good as he could and to exercise every care in tempering it; this he did; then a starter-drill was made with the machine and both were carefully tempered. They were taken into a part of the mine where the rock was the hardest. The hand-sharpened starter was worn out by drilling only $1\frac{1}{2}$ inches of hole, the machine-sharpened drill made a hole not over 6 in. from the other to a depth of $3\frac{1}{4}$ in. This convinced the management that the argument that machine-sharpened drills were not as good as hand-sharpened drills was without any foundation in fact.

I do not know what kind of a machine they use at the mine referred to in your 'Concentrates', but if it is a pressure machine, instead of a hammering machine then it goes without saying that machine-sharpened drills made by pressure are not the equal of hand-sharpened drills.

I trust that you will see fit to publish this letter in full, so that we may hear from others on this subject.

T. H. PROSKE.

Denver, December 10.

Volcanic Ash.

The Editor:

Sir—In your issue of October 12, under 'Concentrates,' you stated that volcanic ash is the dust caused or made by the grinding or colliding of the matter ejected from volcanoes while in mid-air. Now this is such an unusual and startling explanation that I venture to give you what is probably the correct answer. It is a well-established fact that freshly erupted lavas contain a large amount of steam or water of combination which is as essentially a part of them as any other ingredient. Some lavas, especially the more silicious, contain a larger amount of combined water than others and in the case of pitch-stone or obsidian, there is frequently 10 per cent.

Pumice is a silicious lava in which the amount of combined water was so great that it expanded below cooling and leavened it like coke or bread. Volcanic ash is simply an extreme case where the contained steam was sufficient to atomize the lava and blow it out as dust or lapilli. The source of the water or steam which causes the explosion and atomizes the lava is a much debated question, but all the evidence is in favor of it being an integral part of the earth's interior and being a gas it is slowly coming to the surface. Along great fault-planes and mountain-folds there are weak spots which serve as vents for the magmatic steam. The steam is the prime motive force of the volcanic action and acts as a flux to

reduce the fusing point of the rocks along its path. It is only the supersaturated fusions of lava and steam that reach the surface, and the higher the degree of saturation with steam the finer the lava is atomized when it reaches the air.

HIRAM W. HIXON.

Victoria Mines, Ontario, November 18.

[Mr. Hixon's objection is well taken. The definition may be amended by stating that volcanic ash is lava that has been torn into bits by the expansive force of steam, formed from contained water by release of pressure on arrival at the surface. The collision of particles in mid-air will help to break the fragments into dust, but it is a secondary cause.—EDITOR.]

The Fairmont Explosion.

The Editor:

Sir—The facts about the explosion in mines No. 6 and 8 of the Fairmont Coal Co. at Monongah, West Virginia, on December 6, when some 400 miners were wiped out of existence, are beginning to come to light.

After all the gush about "model mines," "excellent inspection," and "every safety device known to man" and the accompanying editorials about the grave limitations of the best engineers, it is a relief, although a sad one, to read the story and the lessons as plainly written by the following facts, namely:

- I. The mines were dry mines.
- II. They contained dust.
- III. They were slightly gaseous, and were in a natural-gas district, where, even if they were gas-free, a pocket or fracture containing gas might be encountered at any time.
- IV. The two mines did not have extra entries, but were connected underground for the purpose of ventilation.

These are four facts easily ascertainable and well known long before the explosion. Was it sufficient that the dust was not thought as explosive as that in the Pocahontas or New River districts? Even the ordinary layman is supposed to know that a mixture of air, coal-dust of any kind, and gas, is as deadly an explosive as was ever invented. Then, too, why was such a death-trap as an underground connection permitted?

Now, when we come to consider the cause of the explosion we have these facts:

- I. Time 10:20 A. M.
- II. Tremendous force of explosion, wrecking houses, timbering, machinery, and so forth.
- III. Path of explosion as shown by bodies, wreckage of props, etc., going *away* from a point near the mouth of No. 6 mine toward the working breast and through the underground connection into No. 8, thence out to the surface, increasing in force as it went.

IV. Immediately preceding the explosion a train of loaded cars had broken loose, dashed down the incline into No. 6 mine and were wrecked at the foot of the slope; and mixed up with the wreckage there was a live trolley wire carrying a high voltage.

A purely gas explosion would have been more localized unless the gas was widely distributed throughout the mines, and in the latter case the gas would have been ignited when the miners first went on duty early in the morning.

It therefore seems extremely probable that the runaway cars in their rapid descent stirred up volumes of dust, which was carried into the mine by their rush, and was there mixed with air and gas, and ignited by the shattered trolley wire. The explosion stirred up more dust and gas, thus gaining headway and force as it trav-

ersed No. 6 mine and reaching its culmination in No. 8, where the greatest damage was done.

Disinterested experts claim that the force and direction of the explosion can be plainly traced, and that the reason of the small damage at the mouth of No. 6 was that the explosion originated near there and had not accumulated the energy shown when it reached No. 8.

As has been so often suggested after previous explosions, there should have been an independent air-course, properly bulkheaded and shielded from the force of any explosion, but which could have been easily thrown into commission after the explosion; thus preventing the lamentable loss of life by after-damp.

What are the lessons brought out anew by this explosion?

Never trifle with gas or dust.

Test for gas every day before the working force goes on duty and also after every shot.

Install and use sprinklers in every dry coal mine, regardless of whether the inspectors demand them or not.

Never connect coal mines as was done in this case.

Appoint inspectors only after a rigid written examination as to their experience and qualifications, and have this examination made by recognized authorities.

S. H. BROCKUNIER.

Wheeling, West Virginia, December 12.

Professional Customs.

[The questions to which reference is made in these letters will be found in our issues of October 5 and 19.—Editor.]

The Editor:

Sir—While on the train today, I penned the following replies to the questions appearing in your issue of October 5:

1. A fee for a specific period, and if this period is exceeded then a pro rata charge for the excess.

2. A written contract is advisable, but an exchange of letters should be sufficient where the client is known to be honorable.

3. Yes.

4. Yes.

5. (a) Yes, except tobacco.

(b) Yes.

(c) No.

(d) It is well to keep an itemized account, for the purpose of making a final statement in case they should be called for. Anyhow, it is a good check. Incidentals may cover a multitude of doubtful expenditures.

(e) Whenever practicable take vouchers.

(f) Yes.

(g) At end of engagement unless otherwise required by the client.

6. It is better *not* to render reports during the progress of the work unless the property is so manifestly good or bad that you can safely do so, for the reason that so many elements enter into a report upon which the expenditure or non-expenditure of money depends.

7. The purchase of shares during an examination is not permissible and not afterward without the knowledge of the client, unless perchance he declined to become interested. The knowledge obtained belongs to the client.

8. It is quite legitimate to examine and take other properties in the district after the work for your client has been completed and report rendered.

9. Absolutely no objection, on the contrary, most desirable.

10. It often happens that a final opinion cannot be expressed until there has been further development.

The matter of cleaning out old drifts, in other words putting the mine in condition for examination, depends entirely upon the contract between buyer and seller. On general terms "it goes without saying" that the mine should be in condition for examination.

GEORGE W. MAYNARD.

Tucson, Arizona, November 16.

The Editor:

Sir—Upon first reading these questions I was undecided as to whether they were really written by an unexperienced man. If they were, he is considerably wiser than he cares to admit; however, they are quite interesting.

First, one correction: he could not be "competent to make the examination" unless he had previously accompanied a seasoned engineer on many trips, in which case he would have learned all that he asks.

1. Fee or salary. As he is going to the tropics the salary basis would prove the most satisfactory to his employers and fairest to himself. There is no danger of his protracting his trip to secure additional pay, whereas if on a fee he would be very likely to hurry up his work in order to get back to the States.

3. This should be interchanged with No. 2; in answer to 3, it should not be necessary to "demand" any money to cover expenses of the trip. If all the cash necessary is not freely offered, the trip should be canceled at once.

2. Having received sufficient money to cover the complete trip, the letter or telegram offering the engagement is sufficient.

4. Most decidedly, but the engineer certainly understands that these implements, etc., belong to the company after he returns and reports.

5. (a) Certainly, except possibly tobacco, and if the trip takes one where tobacco may be unreasonably dear, then I would include that also. (b) He is entitled to first-class accommodations wherever he may go, but not necessarily the best, as he should be thinking about his work, not his stomach. He should go to any expense which may be required to keep him in good health. (c) Most decidedly not; he must travel first-class in order to give the impression that his company is prosperous, in order to keep in good health, and because to do otherwise would be grafting. (d) There need be no charges to 'incidentals,' except possibly at the end of a report to cover small sums spent for street-car fares, tips, not already accounted for, etc. (e) It is necessary and best to take vouchers for any amount, say over ten dollars, which the employer cannot ascertain to be correct himself without much trouble. For instance, there is no sense in taking a voucher for fare paid from Denver to San Francisco or from San Francisco to Panama, as by one minute's use of the telephone the employer can ascertain exactly what it is. But with a fare paid from Panama to some little port in South America the case is different, and a voucher should be taken. Also, there is no reason to take vouchers for money paid for hotel bills, as these items should themselves show whether they are honest or padded. But a bill for grub bought for a trip of a few days or weeks should be turned in. (f) Yes, unless his own ignorance is the cause of his needing such information. (g) This depends on what the employer demands, once a month is certainly enough in any case, but for his own good he should know at any minute just what his cash balance is.

6. How large a fee does the inexperienced young man expect to get for his first examination? There should be enough left over from his "cash for expenses" to nearly cover this item. The company is certainly justified in demanding frequent reports; they have property which

can be attached in case of failure to pay for services rendered.

7. Yes, in case he can do so without hurting financially the people for whom he is working, and in the event that he has time to spare, neither of which is likely to be the case, before his report is rendered. After rendering his report, if it is an honest one, I consider he has a right to deal with the stock as any outsider would.

8. I wonder what he thinks "examining a mine" means. Does he think he can examine a neighboring mine by going through it with the foreman who will show him thousands of tons of fine ore blocked out, but which cannot be milled on account of a shortage of quicksilver at the mill! He won't have an instant's time to "examine" any adjoining mine.

9. There should be no objection, but instead he should do so if his stay in the district is long enough to enable him to become thoroughly familiar with the situation. If his employers suffer through the publication of the truth about the district, this is not an objection, as they cannot be conducting a legitimate business.

10. He is most certainly justified in spending all the money necessary to clean out old drifts, etc., if such work is necessary before the mine can be either condemned or accepted, provided, of course, that the object of the examination is to furnish material for the condemnation or acceptance of the property, its further working, etc. The engineer would be foolish to offer any definite conclusion if the facts obtainable were not sufficient.

CHAS. J. LYSER.

San José, Costa Rica, November 10.

Esperanto.

The Editor:

Sir—Notwithstanding the immense amount of publicity which has been given to Esperanto, the international language, I find that at this time not more than one-tenth of the people of the United States have even a vague idea of its purpose and scope, and perhaps not one in a hundred has a reasonably definite conception of it. As a sort of counter-irritant to the irresponsible criticism which is occasionally circulated by the uninformed, I have printed for free distribution a second edition of 100,000 copies of a small primer, 'Elements of Esperanto,' setting forth the grammar, word-construction, and purpose of the language, and will mail a copy to any person who requests it, sending stamp for postage. While you may not be personally interested, there are thousands of your readers to whom this movement for an international auxiliary language, which now covers every country on earth, will appeal as something more than a fad, and they will appreciate your giving publicity to this letter.

ARTHUR BAKER.

Editor 'Amerika Esperantisto.'

1239 Michigan Ave., Chicago, December 5.

MACHINES for distributing concrete have been employed in street construction work to avoid the manual labor required to distribute the material by means of wheel barrows. The bed carries an 11-ft. cubical concrete mixer, a 16-hp. gasoline engine of the automobile type, and a frame upon which rides a hopper for delivering the material of each batch into the mixer. Beyond the frame projects a 25-ft. boom carrying a track upon which rides a dumping bucket. It is supported by guys, while at the middle is a cross-frame having small wheels which rest on the graded surface of the street. The boom is pivoted at its inner end, and has a horizontal swing of 170°, so as to cover the width of a 50-ft. street. The machine in working order weighs 15,000 pounds.

Japanese Mining Laws.

There are, generally speaking, three kinds of right of ownership to mines, these being: (1) The system of accession, that is to say, the system of ownership by the land proprietor; (2) domainal system, that is to say, the system of State ownership; (3) the system of concession, that is to say, the system of giving concession by the State to the applicant. Japan never adopted the first system; it adhered to the system of State ownership from olden times till quite recently; and when the privilege of working a mine was granted, this concession was regarded as a favor by the Government, given for a certain limited period in consideration of the payment of a royalty. This period, as mentioned in the Mining Regulations issued in 1873, was 15 years. In 1890 the mining regulations were amended; when these new regulations went into effect two years later, the concession system, distinctly establishing the right of permanent working, was inaugurated, and thus the sound development of the mining industry was safe-guarded.

Minerals recognized in the mining regulations are as follows: Ores of gold (excluding alluvial gold), silver, copper, lead, tin (excluding stream tin), antimony, quicksilver, zinc, iron (excluding iron sand), iron pyrites, manganese, arsenic, graphite, coal, petroleum, sulphur, bismuth, chromite, phosphorus, lignite, and asphalt. The last five were added to the list in 1900.

Formerly an alien was disqualified from working a mine and was further prevented from becoming a member of a mining company, so that the right of working mines was reserved exclusively for Japanese subjects. In consequence of the amendment of the mining regulations in 1900 a company, organized by Japanese or aliens, or by both combined, is allowed to work mines, provided such a company is under Japanese laws. This amendment encouraging the formation of mining companies by aliens, has proved a means of stimulating the development of the industry. Contrary to the usage in many Western countries, Japanese law does not recognize the right of priority of discovery. The right of prospecting or of mining is granted to the one who first applies for it whether he discovered the minerals or not. The reason for this is that the fact of an alleged discovery is exceedingly difficult to verify, and Japan considers that accidental discovery does not deserve any special privilege. The right of prospecting carries with it the great privilege that no other person is allowed to apply for the privilege of prospecting for the same minerals in the same area.

The non-recognition of the right of priority of the owner of the land in which a discovery is made is derived from a fundamental principle of Japanese legislation, and must be regarded as a highly reasonable provision. The term for prospecting is limited to one year, to be extended to another year when such extension is regarded proper and necessary. In contrast to this limitation in the period of prospecting, no such limit is enforced in regard to mining. Further, though the right of prospecting cannot be transferred to a third person, or be used as an object of hypothecation, the right of mining can be sold, bought, assigned, or be made an object of hypothecation.

The fact that the concession for working a mine was at first limited to the space of only 15 years, and that this concession was forbidden from being made use of as an object of hypothecation, seriously interfered with the proper development of the industry. The subsequent amendment of the regulations has removed those two grave defects, and today concessionaires and capitalists are enabled to invest large sums in the exploitation of mines.—*Iron & Coal Trades Review.*

Mining Under Adverse Circumstances.

Written for the MINING AND SCIENTIFIC PRESS
By E. McCORMICK.

The subject of this brief article pertains to one of the producing mines of the Arizona Copper Co., an organization employing some 2,000 men in the mining and treatment of copper ores in the Greenlee Copper Mountain mining district of Arizona.

The 225 mineral claims of this company cover 4,650 acres, most of the locations being patented. They are divided into four groups, namely: Morenci, Metcalf, Garfield, and Coronado, all situated north and west of Clifton. The company operates two lines of railroad, one a 7-mile narrow gauge from Clifton to Metcalf, known as the Coronado, and the other a standard line of 107 miles between Clifton and Hachita, New Mexico, known as the Arizona & New Mexico. The former is chiefly for the transportation of ores and concentrates to the smelter at Clifton; the latter puts the various towns of the district in close touch with the outside world.

Ore is taken from the different mines to storage bins on the Coronado railroad, thence to the reduction plant at Clifton, the object of this article being to present an idea of what difficulties have had to be overcome at one of the units before this ore reached a marketable point. The property in question is known as the Coronado. This group comprises 50 claims and is situated $2\frac{1}{2}$ miles southwest of Metcalf at an elevation of 5,820 ft., the elevation of Metcalf being 4,415 and of Clifton 3,465 feet.

The leading mines of this group are known as the Matilda, Crown Reef, Horseshoe, and Boulder, the ore-bodies being of immense size but low-grade, running from 3 to 6% copper. They are chiefly silicious sulphides and occur between granite and porphyry with diabase intrusions in the form of vertical lenses.

All ore is hoisted through the Matilda double-compartment shaft from the various workings. On reaching the surface it is trammed to ore-bins 150 ft. distant. From this point it is taken over a circuitous route around the hills $1\frac{1}{2}$ miles to the top of an incline known as Coronado Junction, by a Porter locomotive hauling ten 2-ton ore cars over a track of 20-in. gauge. At this point the cars are sent down to Metcalf Junction by a gravity tram (see Fig. 1 and 2) in trips of two cars. The length of the tram is 3,300 ft. with a drop of 1,200 ft., some 200 tons being transported in 8 hours. On reaching Metcalf Junction these cars are again trammed to another ore-bin, 200 ft. away, the empties being returned to be picked up by the next trip of loaded cars coming down. This ore is now removed to another set of bins at Metcalf, one mile distant, by another Porter locomotive and train of cars, and finally goes to Clifton over the narrow-gauge.

All up freight, such as timbers and supplies, is handled in the same way; that is, it must come from Clifton and be transferred at Metcalf, loaded into junction cars and be again transferred to the up-cars on the gravity incline, and, on reaching Coronado Junction, it is hauled to its proper destination. Considering the number of times ore must be handled, the relative cost per ton is not high, as the following data illustrate:

2 locomotive engineers.....	@	\$3.25	\$6.50
4 brakemen.....	@	2.50	10.00
1 foreman.....			3.25
4 laborers.....	@	2.50	10.00
1 lever man.....			3.75
Mule expense, feed, and attendance.....			2.50
			\$36.00

Or 18 cents per ton as figured on a daily production of 200 tons. Ninety-nine per cent of the force consists of Mexicans, they having been found to give a relatively high degree of efficiency, as the property presents no difficulties requiring a more intelligent class of labor.

Improvements in the Homestake Mill.

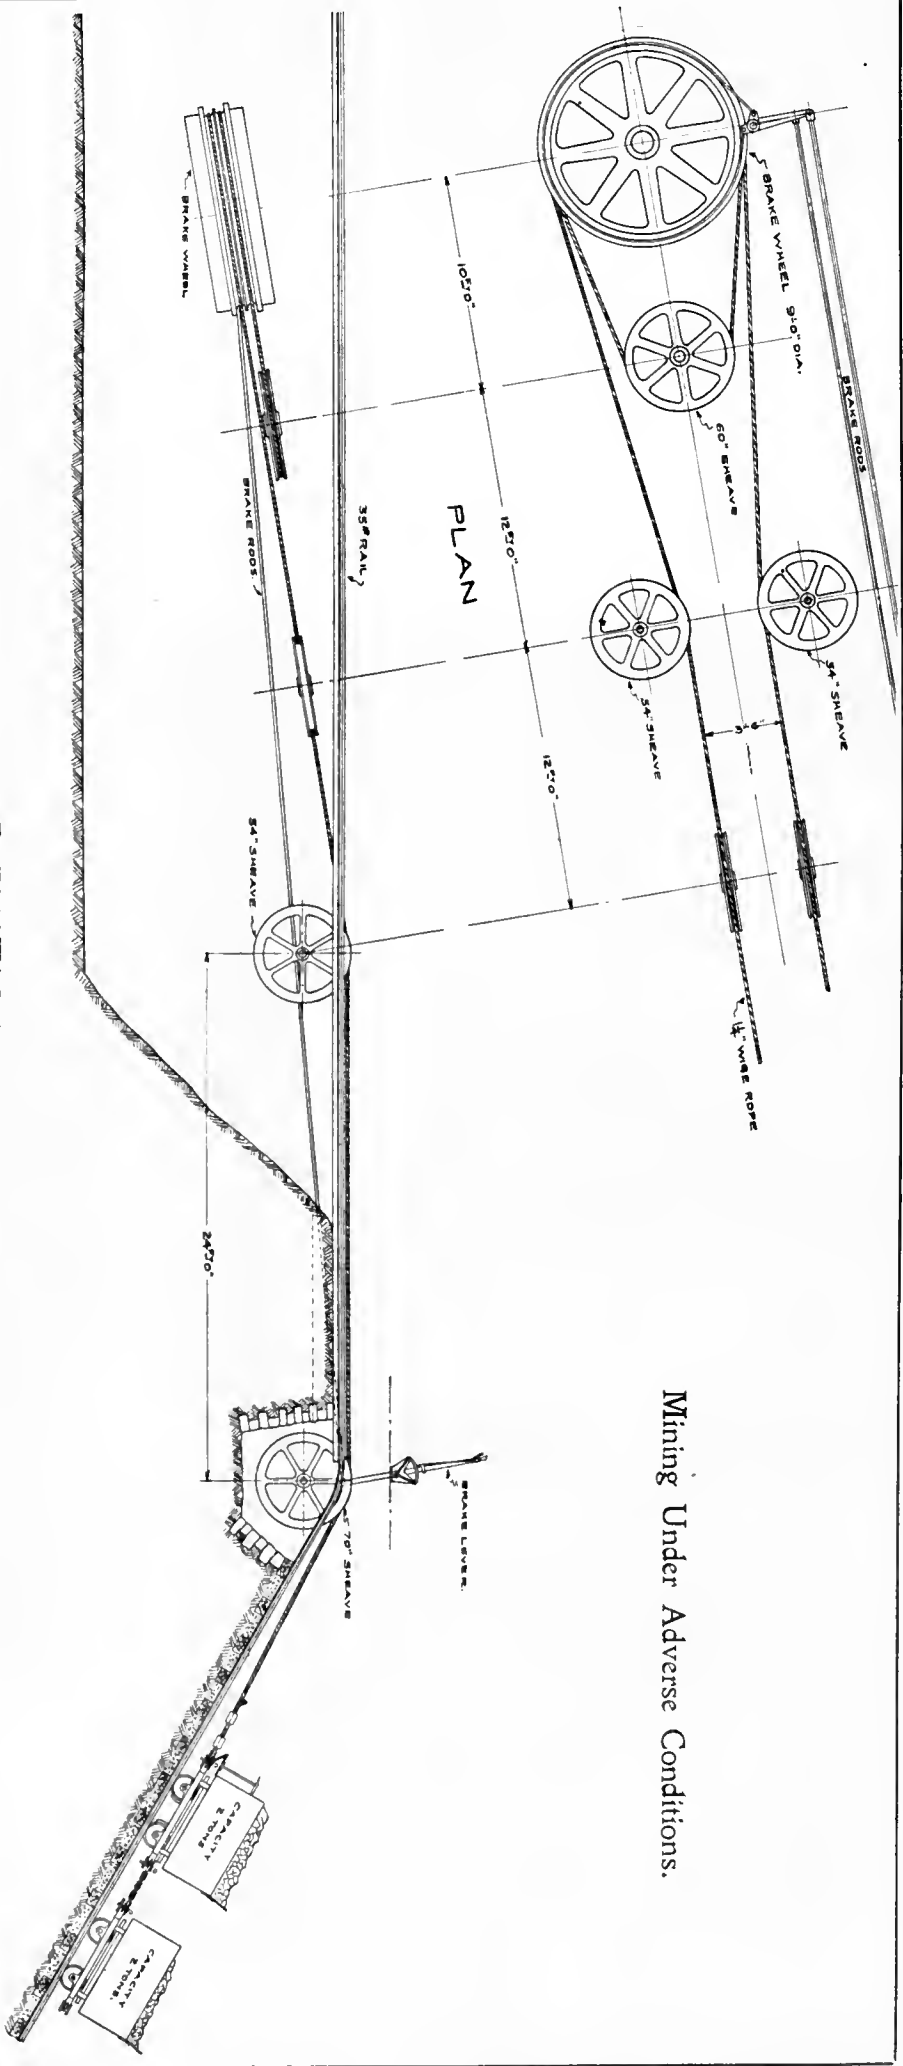

Now that the Homestake mine is again producing its normal mix of ore after the difficulties caused by the fire, the slime plant of this company has reached a point where the showing will approach the work of the future, and C. W. Merrill, superintendent of the mill, designer of the plant, and inventor of the special process that makes it unique, has made public figures relating to the cost and operation. These figures are based on actual operation of the plant for the month of November, during which period 21 presses were completed and running. Today 22 of the 24 filter-presses are in operation and, with the addition of the two others, a still further change will be made in the cost and recovery figures.

During the month of November the plant treated 39,468 tons of slime for a recovery of 88%, by charge and residue assays, and 91% by bullion; while the total costs were approximately 32 cents per ton. The average value of the slime treated was 90 cents. The cyanide decomposition was 0.37 lb. for the first 10 days, 0.33 for the second 10, and 0.325 for the last 10 days. The zinc consumption was 0.2 lb. zinc-dust per ton of slime, while the lime consumption was $4\frac{1}{2}$ lb. per ton. During the last 10 days of the month, which may be taken as a fair sample of the work being accomplished at present in the big plant, an average of 1435 tons of slime was treated per day for a recovery of 89%. The full capacity of the plant is placed at 1600 tons every 24 hours on the slime from the ore mixture now being milled.

One of the most interesting features of the work is the low consumption of power. This was less than one-twentieth of a kilowatt per ton of slime per day, and according to Mr. Merrill this would be reduced to a merely nominal figure were it not for the necessity of compressing a large volume of air in order to oxidize the reducing chemicals in the Homestake ore. This necessity calls for at least 70% of the power used in the treatment of the slime. The explanation of the small amount of power used is the fact that there is no agitation of pulp, and to the further possibility of using a very small bulk of solution; namely, 1 to 1 or less being all that is leached through the slime-cakes.

A thorough test has been made with different ores. During the period of the memorable fire last summer, or rather during that period when the mills were able to resume crushing after a month's idleness, the Homestake was obliged to secure its ore from the open-cut, surface ore being used. While this ore was of lower grade and slower of treatment than that taken from the lower levels, as today, it yielded a slightly higher recovery (up to 93%) as was to be expected from ore containing practically no sulphides.

The slime-plant is today approaching its normal working basis, most of the construction work having been completed and the force of workmen being gradually reduced to an operative basis. The automatic sluicing device, which is one of the important features, has proved entirely successful in this the largest slime plant in the world. The presses hold 26 tons each, while the largest hand-removal presses operated elsewhere have a capacity of but 6 tons each. Mr. Merrill expects that the recovery will shortly be brought up to 90%, or slightly better, and the cost reduced materially, just as the costs per ton at the cyanide sand-plants have been reduced, until today they are less than 25 cents per ton of material treated, as compared with nearly double that figure during the early operations of these plants. The addition of this plant has brought the recovery from Homestake ore to 93% at a total milling cost for crushing, amalgamating, and cyaniding of approximately 50 cents per ton.

Mining Under Adverse Conditions.

ELEVATION.

FIGURE "1"

GENERAL PLAN OF INCLINE.

FIGURE "2"

Cobalt.

Written for the MINING AND SCIENTIFIC PRESS
By FRANK C. LORING.

The Cobalt silver mining district is situated about 300 miles north of Toronto, Canada, and 103 miles north of

Cobalt in Winter.

North Bay, which station is situated on the Grand Trunk and Canadian Pacific railways, thereby connecting Cobalt with Toronto, Ottawa, Montreal, and elsewhere. The Temiskaming & Northern Ontario Ry., constructed by the Ontario Government with the original object of developing the farming and timber regions to the north, runs from North Bay through Cobalt and thence northerly to connect with the Grand Trunk Pacific railroad near Lake Abitibi. The train leaving Toronto at 9 o'clock in the evening reaches Cobalt at 8:45 the following morning.

Silver ore was first discovered at Cobalt in 1903 by men engaged in the construction of the railroad. The phenomenal richness of the ore at once attracted attention, resulting in new discoveries and rapid extension of the ore-bearing area, at present extending 8 to 10 miles easterly and westerly and 4 to 5 miles northerly and southerly. Not all of this area contains mines, but all the mines are within this limit.

The geology of the Cobalt district, as well as all of that portion of Canada is exceedingly complex, extending in age from the igneous complex of greenstones, porphyries, and other rocks of the Keewatin series, through the metamorphosed sedimentaries (Huronian slate and conglomerate) and diabase intrusions of various ages. Limestone also is found in this region.

Veins occur in all the geological formations mentioned. These veins, especially in the Huronian, are exceedingly numerous, and usually of slight persistence both as to depth and lateral extent. There are, however, numerous instances of well-defined and extensive faults, showing strong fissures and a wide zone of faulting. In these fault-zones the rich ore is a minor incident that may recur many times at various depths. The ore mined has been so remarkably rich, and the mining has been so easy, that until recently but slight effort has been made to explore these veins to any considerable depth. The deepest development in the district is about 100 ft., and in most cases ore has been mined to an extreme depth of less than 100 ft. Until the present year mining has been conducted in an extravagant and reckless manner, only the richest ore being saved and marketed; the remainder, amounting in quantity to many times the amount sold, has been thrown upon the dumps.

The ore consists of compounds of cobalt, nickel, and silver, with arsenic, iron, sulphur, and other metals to a less degree, as well as of native silver. This mineral out-

put ranges in value from native silver and 8,000 oz. silver per ton in silver-cobalt-nickel ore in carload lots, and as high as 15% cobalt, 10% nickel, and 50% arsenic, down to a few ounces of silver per ton. Calcite usually accompanies the silver. The rich ore streaks are from the thickness of a knife-blade to as much as two feet. Accompanying these rich streaks, and especially in the fault-fissures, the adjoining rock carries native silver, sometimes for a width of six feet or even more. Continuous ore-shoots extending as far as 800 ft. longitudinally, and to 200 ft. in depth, are found. Usually, however, the occurrence of ore is irregular, and of slight extent. It has been so easy to extract rich ore cheaply near the surface that but few data have been obtained as to the continuity of the ore in depth. During the past year, however, development on the La Rose, Nipissing, Kerr Lake, McKinley-Darragh, Nova Scotia, Foster, Temiskaming, and other properties proves that ore may occur at various depths, and possibly to great depth. Up to the beginning of the present year, about 12,000,000 oz. silver, valued

at about \$7,500,000, have been sold. Little has been received for cobalt, nickel, or arsenic, consequently, no data can be obtained as to the value of these metals pro-

Map Showing Position of Cobalt and New Districts in Ontario.

duced. During 1907, up to October 1, 10,300 tons of ore have been sold, for which possibly \$6,000,000 has been received, almost entirely for silver. The district is now

shipping approximately 1,000,000 oz. silver per month, as well as large quantities of cobalt, for which little is paid. The present market for this ore is in the United States, also at Copper Cliff (Ontario), and in Europe (to a small extent for ore high in cobalt, low in silver). Transportation and treatment charges are from \$15 to \$25 per ton, with deductions of from 6 to 7% of the assay-value of the silver. One smelter pays \$20 per ton for ore carrying 8% cobalt. If ore is sold solely for cobalt 35 to 50c. is paid per lb. of cobalt, according to the percentage, with no allowance for silver. Smelters are being erected and these excessive charges and deductions may cease.

The value of the ore shipped ranges from 100 oz. silver per ton to 8,000 oz. in carload lots. Owing to the small profit in marketing ore of low grade, but a small part of it is marketed. In the process of mining, low-grade ore amounting to many times the number of tons of high-grade ore sold has been accumulated. This ore can be treated by concentration. Two concentrating plants are now in operation, five are in process of construction, and undoubtedly more will be built. When these are ready, the production of the district will be largely increased. There are about 20 producing mines, about as many promising prospects, and a great number of mining claims of problematical value.

During the past year, the principal mines have been equipped with steam plants for furnishing power for drilling and hoisting, substantial buildings have been erected, men of experience have been employed as managers, extensive prospecting and development are in progress. There is much evidence to show that a fair proportion of the veins are lasting, and that in some veins ore will be found at considerable depth. In a few cases blind lodes have been discovered, thereby increasing the range of possibility of successful exploration.

ORE ROASTING.—Some recent experiences in connection with ore roasting at the Great Boulder Perseverance mine, at Kalgoorlie, are of special interest. In operating the duplex roasters it was noticed that as the amount of feed was increased beyond certain limits and it became necessary to fire harder in the front fire-boxes, the ore in the hearth-area between these boxes became overheated, causing it to swell in degree varying with the schistose nature of the ore; this gave rise to what is known as 'balling,' the particles of ore cohering lightly in globular form, and enclosing some of the particles of pyrite. When the ore assumes this condition the normal possibilities of exposing the pyrite to oxidation during the subsequent progression toward the discharge-chutes are much reduced, and an indifferent roast results. To obviate this overheating and minimize the clinkering of ore round the throats of the fire-boxes, the plan was suggested of accelerating the speed of the three sets of rabblers, each set situated respectively between, forward of, and behind the front fire-boxes, and so passing the ore quickly through this zone of excessive heat. The normal speed of these rabblers had been $4\frac{1}{2}$ rev. per min., and this was increased to 9 rev. per min., while the speed of the remaining rabblers was maintained at $4\frac{1}{2}$ rev. per min. As a consequence the depth of ore-bed within the area of accelerated rabbling was much reduced, and the experience of the past five months has demonstrated that 'balling' is now prevented, exposure to oxidation is facilitated, no ore is thrown onto the bridges of the fire-boxes, and clinkering is greatly minimized.—*Journal of the Chamber of Mines of Western Australia.*

THE first mining and smelting of lead in what is now the United States was near Falling creek, Va., to supply the local demand for bullets and shot.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

Where a mine-owner failed to comply with the statute requiring him to guard his employees from injuries by reason of dust, bad air, explosives, etc., he was not permitted to plead contributory negligence or assumption of risk in an action by a miner for an injury caused by failure to comply with the statute.

Bolen-Darnall Co. v. Williams (Ind. Terr.), 104 Southwest, 867, Sept. '07.

The foreman of a mine whose duties were confined to the underground part of the mine was not the superintendent of the colliery within the meaning of the Pennsylvania statute for the purpose of giving notice to the mine inspector of the district.

Corgan v. Lee Coal Co. (Pa.), 67 Atl. 655, May, '07.

A coal miner with eleven years' experience, and who had worked for eighteen months in a particular mine was held competent to testify as to the sufficiency of a sprinkling machine used by the mine owner to keep down explosive dust.

Bolen-Darnall Co. v. Williams (Ind. Terr.), 104 Southwest 867, Sept. '07.

A mule, driven by a miner in hauling cars of coal out of a mine, took fright at an object properly in the mine, broke loose from the car and ran away. The pit-boss represented to the driver that the mule was only frightened; that ordinarily he was gentle and could again be worked and induced the driver to take it back into the mine, hitch it up, and finish the work; the miner did so, under protest, and relying upon the opinion of the pit-boss as to the gentleness and safety of the undertaking. He continued driving the mule, hauling out a number of loaded cars, when later in the day the animal again became frightened at the same object, by reason of which the driver was thrown under the car and received serious injury. It was held that the miner assumed the risk with knowledge of the danger, and could not recover.

Milby Co. v. Balla (Ind. Terr.), 104 Southwest 860 Sept. '07.

The rule that the master is required to use ordinary care to provide a reasonably safe place and appliances for work, and the servant to exercise like care in using the place and appliances, and, if he becomes aware of any defects therein not known by the master and continues and is injured he cannot recover, applies to mine owners and miners, as well as to other relations of master and servant.

Milby Co. v. Balla (Ind. Terr.), 104 Southwest 860 Sept. '07.

The burden of making well reservations was said to be on the lessee or his assignee where the lease provided for the construction of seven wells on a seventy-acre tract of land, and that the lessor could not arbitrarily set off 20 acres for two producing wells, and quiet his title to the remaining tract after the expiration of the time for the construction of all the wells. The lessor could only demand that the lessee make the reservation within a reasonable time, and on his failure to do so could maintain an action for such apportionment by the court.

Pittinger v. Ramage (Ind.), 82 Northeast, 478, Nov., '07.

The validity of both placer and lode locations depends on the discovery of mineral within the limits of a mining claim.

New England Oil Co. v. Congdon (Cal.), 92 Pac. 180, Oct., '07.

It is not necessary that the discovery of mineral should precede the location of a mining claim in order to sustain the location.

New England Oil Co. v. Congdon (Cal.), 92 Pac. 180, Oct., '07.

Prolonging the Life of Mine-Timbers.

By JOHN W. NELSON.

*In 1906 the Forest Service, in co-operation with the Philadelphia & Reading Coal & Iron Co., made a series of experiments to determine the best methods of prolonging the life of mine-timber. The results of the study are given herewith.

Forty-five per cent of mine-timber is destroyed by decay, while breakage, wear, and insects together destroy the remainder. (See Fig. 1.) It is decay and its prevention in which the Forest Service is more especially interested. By direct experiment it is being shown that both oils and chemical salts, and the precaution of peeling and seasoning, prolong the life of the timber. The point of first practical importance, then, is: What method of handling and what preservative treatment will give the greatest service at the least expense?

Decay or rot is produced solely by certain organisms called bacteria and fungi. Germs or spores which produce decay may gain access to the timber at any time before or after it is cut, though for the most part the disease is contracted in the mines from decaying timber near-by. In untreated timber, rough surfaces of bark and wood furnish a foothold for the spores, which subsequently germinate and attack the tissues. Spores may also enter timber only superficially treated through checks, cracks, or nail wounds.

For a fungus to exist it must have a

FIG. 1. Diagram showing relative importance of the causes of destruction of mine timbers.

FIG. 2. View in a Pennsylvania coal mine, showing the great amount of timber that is used. (Drawn from a photograph.)

definite amount of air and water, food and heat. If mining conditions were such that the timber would be kept always wet or always dry, it would never decay. It is the alternating wet and dry conditions or continuous dampness that produce rot.

Ventilation is a large factor in the life of timber. Poorly ventilated gangways and air-passages, with a fair degree of moisture and a fairly high temperature, are favorable to fungus growth, and hence to rapid decay.

A large percentage of the gangway timber used in anthracite mines is broken by the 'squeeze' and 'crush' of coal and rock. Where timber is certain to be broken in a few days or weeks, expensive preservative treatment would not be economical. However, in many situations the timber is broken only after it has been greatly weakened by decay, and for these cases an inexpensive form of treatment may properly be considered.

Cross-ties in main haulage ways are constantly worn by the rails and by the feet of mules. Wooden rollers, drum laggings, etc., have to be replaced when worn by the contact of ropes and cables. A preservative treatment

is obviously not suitable for timber subjected to this sort of wear.

The important part which insects play in the destruction of timbers is rarely realized. They are for the most part brought into the mines with the timber. Regular and thorough inspection and the rigid condemnation of insect-infested timber would therefore greatly reduce the loss from this source. Insects bore into sound wood and greatly weaken it and, moreover, leave holes or galleries which encourage the entrance of wood-destroying fungi. A good preservative treatment will protect the timber from insect attack, as well as prevent decay. If the bark is removed from timber soon after it is cut, it will not be attacked by wood-boring insects until the wood becomes old and dry, after which it may be attacked by 'powder post' and other borers.

In the handling of timber for its many uses in the mines there is some unnecessary waste. Though decay or a fracture is often confined to but one part of a set, the entire set is rendered useless. Therefore if it is possible to preserve the threatened part, the whole prop or set may be saved. Again, in certain situations the sizes of timbers may often be materially reduced provided they are kept sound. Under present conditions the timber is often large enough to do its work after decay has progressed to a considerable depth. Instead of off-

setting this decay with sizes larger than necessary, smaller treated timbers may be used with economy.

The utilization of waste timber has been carefully investigated. Short sections of broken and partially decayed round timber have been split into lagging with some success. Worn-out and broken planks, sills, rollers, etc., have been profitably disposed of to railroad companies as fuel wood for locomotives with the additional benefit of cleaning up the collieries. Worn-out drum lagging and short ends of sound gangway timber, formerly regarded as useless, have been sawed into short mine plank, car lumber, pulley bearers, and slab plank. Rough slabs from the mills have been split into lagging and the refuse of the mill consumed as fuel.

Sets of round gangway timber of 13 in. diam. were chosen as a basis for the experimental work. These sets, which are used for supporting the main haulage ways, consist of two legs (9 and 10 ft. long) and a collar (from 6 to 7 ft. long). They are usually placed in gangways at intervals of 5 ft. through miles of passages. Each set represents about 26 cu. ft. of timber, and one gangway frequently contains 1,000 sets. Ten gangways to a colliery is not an unusual number; and since the average

*Abstracted from Circular 717, Forest Service, U. S. Department of Agriculture.

life of the timber in these gangways is hardly above two years, the consumption of timber in anthracite operations is vast (Fig. 2).

It was early realized by the Forest Service that a successful preservative treatment would effect great saving in the use of this gangway timber, and the chief object of the experimental work was to learn to what extent gangway timber would be benefited by peeling, by seasoning or drying out, and by treating with a wood preservative. The comparative value of different kinds of wood for gangway timber was also considered. Pennsylvania pitch pine and Southern loblolly pine were the

the weight of the water evaporated. The time of the year greatly favored rapid seasoning. The short lengths into which the timber was sawed gave a large drying surface in proportion to volume, and longer sticks would season more slowly. (Fig. 3.) Table 1 gives a synopsis of this test:

TABLE 1.

	%
Loss of green weight by peeling	8.1
Loss of green weight by seasoning	35.1
Peeling and seasoning	43.2

If a mining company handles its own timber from the woods to the mines, the saving in freight made possible by peeling and seasoning can readily be estimated. Labor is the principal factor in the cost of peeling, while the cost of seasoning must be represented by the loss of interest on the capital invested in the timber during the seasoning period. However, these additional items of expense are more than offset by a maximum reduction in freight of from 30 to 40% and by the far better condition of the timber with regard to both its life at the mines and the readiness with which it will take preservative treatment. The peeling of timber at the mines has been unsatisfactory and expensive, because of the limited amount of yard room and the accumulation of bark. The following considerations favor peeling in the woods: (1) The saving in the cost of freight due to peeling and seasoning; (2) the saving of yard room at the mines; and (3) the prevention of fungous

FIG. 3. Diagram showing percentage of loss of green weight by seasoning.

principal experimental timbers, since these species furnished the bulk of the round timber used in the mines of the company. Red oak and chestnut were tested as species suitable for planting in the anthracite region of Pennsylvania.

Experiments have shown that peeled timber is superior in durability to unpeeled timber. The space between the bark and the wood especially favors the development of wood-destroying fungi and is a breeding place for many forms of insect life. When, after placement in the mines, the bark begins to flake off, the timber has already begun to decay. The cost of peeling timber before it goes into the mine ranges from 20 to 50c. per ton of wood, according to local conditions and the kind of timber.

Seasoning or drying gives mining timber greater strength and durability. A stick of wet timber has only about one-half the strength of a similar stick absolutely dry. Though it is not practicable for mining companies to hold their timber until it is absolutely air-dry, peeled timber will dry sufficiently in a few months to gain in both strength and durability. From two to four months is necessary for proper seasoning.

To learn the possible loss in weight in round gangway timber, due to peeling and seasoning, a test was conducted at one of the collieries of the company. Representative sticks of Southern loblolly pine, averaging from 11 to 13 in. diam. and from 9 to 10 ft. long, were chosen. This timber was weighed immediately before and after peeling, to determine the weight of the bark. It was then weighed every two weeks until seasoned, to learn

disease and insect attack by early peeling.

Peeling and seasoning mine timber unquestionably increase its durability. However, in order to prolong its life to the fullest extent, a preservative treatment is necessary. (Fig. 4.)

Impregnated wood resists decay because the preserva-

FIG. 4.

tive is antiseptic and excludes the moisture necessary for fungus growth. Timber used in the mines was treated with a variety of preservatives under several methods of application. Both green and seasoned timbers were treated to determine both the relative value of the treatments and the best method of handling preparatory to treatment. If treated at all, the timber must be peeled. Table 2 shows: (1) The method of treatment; (2) the preservative applied; (3) the cost of the preservative; (4) the cost of the treatment, both for an average set of gangway timber and per cubic foot.

Brush treatments with both creosote and carbolineum were applied in two coats to the Pennsylvania and Southern pines. A large flat brush and a kettle of the hot preservative are all that is required for this treatment. A small amount of the preserving fluid suffices, but the cost

TABLE 2.				
METHOD.	Preservative.		Cost of treatment.	
	Kind.	Cost.	Per set (25.8 cu. ft.)	Per cu. ft.
Brush	Creosote (dead oil of coal tar).....	\$0.03 per gal.	\$0.40	\$0.015
	Carbolineum	0.70 per gal.	1.15	0.045
	Salt solution, magnesium chloride, 15%.....	0.01 per lb.	0.50	0.02
Open tank without pressure.	Zinc chloride solution, 6%.....	0.04 per lb.	0.90	0.035
	Creosote	0.03 per gal.	2.85	0.11
	Zinc chloride solution, 6%.....	0.04 per lb.	1.90	0.075
Cylinder with pressure.	Creosote	0.03 per gal.	3.85	0.15

of application in proportion to the results obtained is considerable. For small individual operators who can not

was briefly as follows: Green, partially seasoned, and thoroughly seasoned timber was lowered into the tank and immersed in creosote, or in a zinc chloride or salt solution, at a temperature of from 90° to 120° F. The temperature of the creosote was raised by the coils to from 212° to 220°, and that of the zinc chloride or the salt solution to about 212°. In no case, however, was the temperature allowed to go above 240° for fear of injuring the fibre of the timber and so decreasing its strength. When this hot bath was over the steam was turned off, and the timber was allowed to stand until the liquid cooled to a temperature of from 170° to 100° F. The periods of heat and of cooling were varied for each kind of timber and for each stage of its seasoning. The time required for the cooling operation, which depended largely upon the temperature of the atmosphere, was usually from 3 to 12 hours. For the whole treatment the time varied from 6 to 20 hours.

The theory of the open-tank process may be given in a few words. The heat of the preservative expands and expels a portion of the air and water contained in the cellular and inter-cellular spaces of the wood tissue, and as the preservative cools there is a contraction and condensation of the air and water that remain. To destroy the partial vacuum thus formed, the liquid is forced by atmospheric pressure into the cellular and intercellular spaces, a process aided, of course, by capillary attraction. In point of fact, therefore, the hot bath merely prepares the wood for absorb-

FIG. 5. Comparative penetration in seasoned and green loblolly pine. Both sticks were given the same treatment. The seasoned piece has practically full penetration. (Drawn from a photograph.)

afford the cost of a large plant, brush treatments are feasible and economical.

The disadvantages of brush treatments are:

- (1) The difficulty of completely covering the timber and filling all checks and cracks.
- (2) The slight penetration secured. The subsequent checking or opening of the timber may often allow disease to pass through the shallow exterior band into the untreated interior wood.

Pitch pine and loblolly pine have been most successfully treated with both creosote (dead oil of coal tar) and a 6% solution of zinc chloride by the open-tank process.

The experimental open tank was, for the most part, constructed from old material already in the possession of the company. A section of an old boiler, 34 in. diam. and 13 ft. long, was set vertically in the ground to a depth of 5 ft. This tank had a double bottom, separated by a space of 1 ft. Between the two bottoms a coil of 1-in. pipe 20 ft. long, carrying a steam pressure of 110 lb. per sq. in., furnished the heating surface necessary to give the preservative fluid a maximum temperature of 240° F. This coil was connected by a 1-in. pipe to a 10-in. steam main 75 ft. distant. The timbers, which were placed vertically in the tank, were immersed by attaching a circular weight to their lower ends. The timbers were lowered into and hoisted from a tank by means of a small hand derrick with a swinging arm.

The open-tank treatment as given in this experiment

FIG. 6.

ing the preservative, and the actual impregnation follows as the preservative cools. The ease and effectiveness with which timber can be treated depend upon the kind of wood and its degree of dryness.

MINING AND METALLURGICAL PATENTS.

Specially Reported for the MINING AND SCIENTIFIC PRESS.

SELF-TIGHTENING ROCK-DRILL CHUCK.—No. 871,972; James A. Thompson, Edwin M. Mackie, and Percival F. Doyle, Chicago, Illinois.

In a self-tightening rock-drill chuck, the combination of a chuck body having an apertured face, a bushing therefor having an inner relieved portion intermediate its ends, and a slot opposite said relieved portion, means for resiliently securing said bushing in said aperture, a chuck key engaging said slot and aperture and having an inclined top, a device engaging said chuck body and chuck key to maintain the parts in assembled condition, and means for limiting the forward movement of said device when the chuck key is removed.

MAGNETIC SEPARATOR.—No. 871,365; Alfred Schwarz, New York, New York.

In a magnetic separator the combination of a table having a riffle board supported thereon, electro-magnets above and having their polar faces in proximity to said board, said magnets being disposed in independent rows, means to feed the material to be separated in proximity to the first row of magnets, means to energize and de-energize said rows of magnets successively to separate a given mass of magnetic particles from the non-magnetic, and to transport the former across the table by alternately attracting and releasing the same so as to fall within the fields of successive rows of magnets, rows of electro-magnets below, and having their polar faces in proximity to the under side of said board, and means to energize and de-energize said magnets alternately above and below the riffle board.

ROCK-DRILLING MACHINE OR ENGINE.—No. 872,418; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.

In a drilling or boring machine or engine, a power cylinder containing percussive apparatus and provided with a rear extension, a feed-cylinder into which the rear extension

is engaged, a piston carried by said extension, a port for supplying air to the apparatus, a port for supplying water under pressure to the rear extension, and a valve for connecting either of said ports as desired to said extension.

ORE-CONCENTRATOR.—No. 872,555; John R. Capps, Middletown, California.

In a concentrator of the character described the combination with a stationary bowl having a central orifice in the bottom thereof and a hollow frusto-conical extension upon the bottom of the bowl and surrounding the orifice, said extension being fixed within the bowl and constituting an outlet for tailing; of a tangentially disposed pipe inclined downward toward the bottom of the bowl and opening into the bowl, said pipe being disposed to direct fluid under a head into the bowl to produce a whirling action, an outlet pipe extending from the bowl adjacent the top thereof, a flexible hose extending from said pipe, and discharging means connected to the bowl adjacent the bottom thereof, the upper end of the frusto-conical extension being located in a horizontal plane extending below the outlet pipe.

ELECTRODE.—No. 872,878; Robert J. Wisnom, Virginia City, Nevada.

An anode comprising a metallic oxide and a support for the same formed of vegetable fibres. An anode comprising peroxid of lead in a granular form and a support for the same formed of vegetable fibre. A non-conducting envelop divided into a number of vertical pockets, a transverse pocket connecting them at the top and a metallic oxide inclosed in said pockets. An anode comprising a non-conducting envelop divided into a number of vertical pockets with a transverse pocket connecting them at the top, a metallic oxide inclosed in said pockets and a wire in said transverse pocket.

WATER-SUPPLYING ATTACHMENT FOR ROCK-DRILLING MACHINES.—No. 872,996; Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.

In a rock-drilling machine or engine, in combination, a cylinder, a swivel mounted on the front end thereof, a drill steel slidably and non-rotatably positioned in the front end of the cylinder, and formed with a longitudinal port leading to the cutting end, ports placing the swivel in communication with said longitudinal hole and means for conducting water to the swivel.

The House of Braun.

Among the first of the newly constructed re-enforced concrete buildings to be occupied in the wholesale district in San Francisco is the five-story building at 576-584 Mission St., built for F. W. Braun, dealer in assayers' appliances and supplies, under the management of W. B. Roslington. The general offices, salesmen, and attractive counter displays are on the ground floor, while the other floors are given over to the storage of a large stock of apparatus, chemicals, and supplies. The parent house of F. W. Braun is at Los Angeles, temporarily situated at 409-415 East Third St. For their permanent quarters F. W. Braun has purchased a site on East Third St. with a frontage on the Santa Fe railroad tracks. Here Mr. Braun plans to erect a plant to accommodate his extensive business. The illustration shows the plan to be followed. The buildings, constructed of re-enforced concrete, will be ready within twelve months. A four-story and basement building will occupy the Third St. frontage.

In the basement will be stored commodities requiring a uniform temperature and moisture. The main floor will be finished for general offices, purchasing and sales departments. The second floor will be the assembling room. The third and fourth floors will be used for the manufacture of instruments of precision for physical laboratories, chemical and scientific apparatus, and for a scientific glass-blowing department. Adjoining the main building in the rear will be a two-story warehouse, with a track frontage of about 150 ft. This building will be equipped with loading-platforms for shipment of goods by cars or wagons. A modern manufacturing building, fully equipped to manufacture this company's line of laboratory machinery and apparatus, will be built in the rear of the warehouse. The plant will include an iron and brass foundry, and a sheet-metal and wood-working department. Another interesting feature of the plant will be the installation of a series of fire-proof chambers, with steel storage-tanks, for commercial liquid acids and industrial alcohols and ammonia, making it feasible to bring these commodities from the place of production in tank-cars, and transfer on arrival by pressure-pipe service, directly into the storage-tanks, reducing the cost of handling to a minimum. Mr. Braun is the owner of valuable patent rights, covering useful and popular appliances used in chemical and metallurgical laboratory work and he has developed a world-wide demand for his manufactures.

Catalogues Received.

THE BLAISDELL CO., of Los Angeles, Cal., has issued 'Catalog H, El Oro Tube-Mill Lining,' giving some useful information in regard to tube-mill linings.

THE KILGORE-PETELER CO., of Minneapolis, Minn., has sent us 'Catalogue No. 5; Peteler Industrial and Mine Cars, Narrow-Gauge Railways.' This describes the ore cars, car wheels, and buckets for earthwork excavations, manufactured by this company.

THE PENNSYLVANIA SALT MFG. CO., of Philadelphia, Pa., has issued a catalogue entitled 'The Wedge Furnace for the Mechanical Roasting of Ores.' This furnace is designed for mechanically roasting pyrite fines and sulphide ores, including blende.

THE SULLIVAN MACHINERY CO., of Chicago, has published a catalogue entitled 'The Excavation of Rock by Machinery;' this describes the air-drills, channeling machines, air hammer-drills, and also less fully the air-com-

pressors manufactured by that company. The instructions to drill-runners are well worth reading by all users of rock-drills.

THE UNION IRON WORKS CO. has sent us two catalogues, 'The Merton Roasting Furnace' and 'Low Sample Crusher and Sample Grinder.' In the first is described the Merton furnace, which has been used at many mills in Australia. While it is new to this country, it has been used for some time there. The Low Sample Crusher and the Low Sample Grinder are especially designed for such work as crushing samples taken while examining a mine; both can be run by hand.

A New Mine-Car.

An order was placed recently with the Arthur Koppel Co., manufacturers of industrial railway materials, for 200 mine-cars by the New River Pocahontas Con. Coal Co. The first sample car of the order was ready for inspection on

November 15, and a committee consisting of several mine superintendents of the vicinity went to Koppel to inspect the car. The committee examined the car in detail and then announced that it was the best they had ever seen. An additional order for 200 cars was immediately placed with the Koppel Company.

This car is of all-steel construction. It is a very low car with large capacity, the over-all height from top of rail being only 30 in. and the capacity 57½ cu. ft. The gauge is 44 in. A special feature in the design is the round buffer, built of special steel channel having small depth and very wide flanges. At the ends the buffer channel is bent semi-circularly and projects beyond the car, to give clearance between the corners of the cars on curves. Between the ends the buffer channel is continued clear through the car, making a continuous buffing column capable of carrying all end-shocks from car to car, without transmitting the whole strain to any particular car. This feature is similar to that used on standard railroads.

The side over-hang has been well stiffened and gives the car its large capacity. The large radial corners of the car-body facilitate the discharge of the load. The door at one end is of the lift type, and is well stiffened to give the necessary rigidity. The wheels are 16 in. diam. with axles and bearings of a special patented self-oiling type.

These cars are for general coal-mine service, transporting the coal from the workings to the tipples, where they are automatically dumped. A special device has been fastened to the bottom of the car to catch the dogs on the chain-hoist used at the tippie-incline. This car is light, rigid, and serviceable; considering its low over-all height and high capacity, together with its substantial buffers, it is considered most suitable for use in mines where a narrow-gauge railway can be operated.
